FOREWORD

No book treats the subject in a comprehensive and exhaustive manner giving the rules of universal application to be adopted in the several stages of the different Directional Calculations, though Directions are pre-eminent for judging nativities. In this book I have endeavoured to do so, and, therefore, to render all Directional Calculations lucid. It is for the reader to judge how far I have succeeded in my attempt.

I have raised certain questions in regard to some kinds of Directions, such as Converse Directions of all kinds, Primary Mundane Directions to the Horizon, Primary Zodiacal Directions, and Directions of the Angles. I trust the reader will agree with me in my contentions.

To complete my "Century Tables of Houses", its Part IV for latitudes 61° to 66° 33' is already being printed and is expected to be published before the current year ends. The Essentials of Hindu Judicial Astrology is also in the Press, and it may be published even earlier.

140, BROADWAY,
MADRAS,
20th September 1933.

M. VIJAYA-RAGHAVULU.

TEXT-BOOK ON

DIRECTIONAL CALCULATIONS

LESSON I-INTRODUCTION

- 1. The Standard Nativity—Mathematical subjects are best taught when they are illustrated with solved problems exemplifying the various principles. As it would conduce to the better understanding of the subject to take a single horoscope to illustrate all the calculations, I propose to take up that of George V for the purpose. He was born in Marlborough House, London, 51° 20′ N. geocentric latitude, and 0 hour 0 minute 37 seconds W. longitude, at 1.18 A.M., G. M. T., on Saturday, June 2/3, 1865. And for the purpose of providing exercises to be worked out by the reader, I shall take up the horoscope of one born at 12° 59′ N. geocentric latitude, and 5 hours 21 minutes E. longitude, at 8.41 A.M., L. M. T., on Wednesday, December 13, 1871, which will be referred to as the standard nativity.
- 2. Zodiacal Positions of Bodies—The zodiacal position of a body is its position in the ecliptic circle, and is expressed by the two co-ordinates, the celestial longitude and celestial latitude. The determination of the zodiacal positions of bodies at birth, is discussed in Lesson IV of my Text-book on Mathematical Astrology. They are known as the radical positions. Let us agree to state longitudes in degrees and minutes reckoned from the First Point of Aries, dropping the names of the zodiacal signs, e.g., 207° 46′ for 27 = 46. The zodiacal positions of celestial bodies at George V's birth were as:—

Body	Lon	g,]	Lat		Body	Lon	ıg.		Laţ		Во	dy	Lo	ng.		Lat.
0	720	26′	0°	0'		P	39°	39'	1°	29	s.		r,	204°	6′	2°	39'N.
a	181	3	2	27	S.	₫	125	35	1	26	N.		វរូរ	.88	37	0	12 N.
¥	48	29	3	17	S.	71	265	40	0	26	N.		(p	10	1.0	. 1	30 N.
Exer	ciso (1)	I7i	nd	the	20	diacal r	osition	s of	all	the	n ho	diés	in	the s	tanda	rd i	nativity

8. The Zodiacal Positions of Cusps of Houses—The zodiacal cusps or the first points of the zodiacal houses have only longitudes and no latitude, being ecliptic points. The determination of the zodiacal cusps is fully gone into in Lesson V of my Text-book on Mathematical Astrology. They are also found readily worked out in my Century Tables of Houses in which all the non-angular,

namely, the second, third, twelfth and eleventh, as well as the angular, namely, the first and tenth cusps, are given correct to the first place of decimal, for every integral minute of sidereal time, that is, for every fifteen minutes of arc in R.A.M.C. The R.A.M.C. at George V's birth was \$70° 51′ 33″, and the geocentric latitude of the birth place was 51° 20′ N. The longitudes of the cusps at R.A.M.C. 270° 51′ 33″, and for N. geocentric latitude 51° 20′ as given in Century Tables of Houses are:

Cusp	Long.	Cusp	Long.
X	270° 47°3′	. I .	2° 2.7′
XI	289 7'2	II	48 41'2
XII	313 40'8	III	72 36'6

Exercise (2)-Find the longitudes of the cusps of houses in the standard nativity.

4. Zodiacal Map—The zodiacal positions of bodies and of cusps at a birth are best presented in the form of a map of the heavens at the moment.

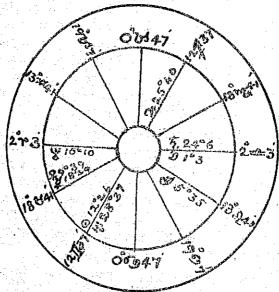

Fig. I-The Zodiacal Map at George V's birth.

Exercise (3)—Brect the zodiacal map of the heavens for the standard nativity.

5. Mundane Positions of Bodies—The mundane position of a body is its position in the heavens in relation to a particular birth place on Earth. It may be stated in one of two ways, (1) by the angular distance at which the body is from its nearer meridional half, which is spoken of as its upper meridional distance (U.M.D.) or its lower meridional distance (L.M.D.), or (2) by the angular distance at which the body is either forwards (anti-clockwise) from the case of

its mundane house, termed the cuspal distance forwards (C.D.F.), or backwards (clockwise) from the cusp of its next anti-clockwise house, termed the cuspal distance backwards (C.D.B.) The determination of the radical mundane positions is dealt with in the latter part of Lesson VI of my Text-book on Mathematical Astrology. To find these positions, the R.A.'s, the declinations and the semi-arcs of bodies have to be first determined, which is gone into in the former part of Lesson VI of my Text-book on Mathematical Astrology. The determination of the mundane cusps is included in the above solution. The mundane positions of the bodies in George V's nativity are:—

Body M. D. Position. Body M. D. Position, Body M. D. Position.

- Ψ 80° L 57′ I 5° 44′ ⊙ 19° L 54′ II 19° 32′ α 89° L 7′ VI 26° 54′
- 9 53 L 9 I 19 41 W 2 L 22 III 16 34 5 67 U 36 VII 13 46
- Exercise (4)—Find the mundane positions of all the bodies in the standard nativity.

6. Combined Mundane Map—The mundane positions of bodies have not till the publication of my Text-book on Mathematical Astrology been presented in the form of a map, because each body has its own set of twelve mundane houses, the R. A's. of whose cusps, except the tenth, vary. So, each body has its own mundane map, and consequently the whole set of mundane maps is omitted as being not feasible. This omission necessitates the calculation of mundane directions with the aid of zodiacal maps. Such a practice necessarily gives rise to much confusion, and leads to errors and oversights in directional calculations. For example, Mercury in George V's nativity is in the first zodiacal house but in his second mundane house (see Fig. I and II). Should we elect to omit the degrees and minutes in the R.A.'s of the cusps of the mundane houses of different bodies, and to give only their C.D.F.'s in the mundane houses occupied by them, we can erect a single combined mundane map with the mundane positions of all bodies shown in it. Such a combined mundane map will be helpful in working out mundane directions, as will be seen presently in the discussion of mundane

Exercis (5)—Erect the combined mundane map for the standard nativity.

7. Speculum.—The celestial longitudes, the celestial latitudes, the right ascensions, the declinations, the meridional distances, the semi-arcs, the mundane house-spaces, the cuspal distances, and the horizontal distances of the different bodies when determined may be entered in a tabular statement called the speculum, for ready reference in directional calculations. The speculum for George V's nativity is given in Schedule I below.

directions. So I have designed one on the lines indicated above, which is given

Exercise (6)—Prepare the speculum for the standard nativity,

on Page 5 for George V's nativity.

Speculum of Bodies taken with their Latitude.

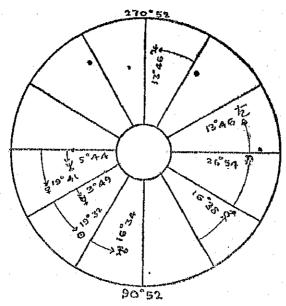

Figure II—The Combined Mundane Map for George V's nativity.—The figures are the C.D.F.'s of the bodies,

8. Zodiacal and Mundane Aspects—All about the determination of all the zodiacal aspects and parallels and of all the mundane aspects and parallels between the several pairs of bodies, are very fully set out in Lesson VII of my Text-book on Mathematical Astrology. The reader is strongly recommended to master the subject, else he will feel a great deal of difficulty in understanding the subject of directional calculations. In fine, the subject of aspect determination is the foundation on which rests the problem of calculating directions.

In George V's nativity all the Zodiacal Aspects are :-

							The same and the same same same same same same same sam

Exercise (8)—Determine all the mundane aspects in the standard nativity.

[±] Signifies the Biquintile aspect.

- 9. Directions—At the birth of a child a very few radical aspects stand completed (see Art. 8). As time rolls on, bodies change their positions and are brought to aspects of the radical or birth positions of their own and those of other bodies. This dislocation of the birth positions of bodies is brought about by two phenomena. The first is the eastward axial rotation of the Earth, appreciated by us as the apparent diurnal rotation of the heavens, which causes celestial bodies to appear to rise in the east, to culminate at the mid-heavens, and to set in the west, and so to shift from their birth positions. The second is the eastward annual motions of bodies round the Sun, and of the Moon round the Earth, which causes celestial bodies to shift eastwards or anti-clockwise. In either case the mundane positions of bodies at birth are dislocated. The change in the positions of bodies necessary to bring them into new aspects of the birth positions of other bodies or of their own radical positions is termed a direction. Therefore, a direction is an aspect to be formed in the future. In radical aspects we note the aspects of bodies to other bodies, all taken as they stood at birth, but in directions we note the aspects of bodies taken at their subsequent positions to themselves or other bodies as they stood at birth or at a subsequent moment.
- The Five Elements of a Direction—In every direction there are five elements. (1) The body that is moved is known as the directed body (D.B.). Any one of the seven planets, Mercury, Venus, Mars, Jupiter, Saturn, Uranus and Neptune, and of the two luminaries, the Sun and Moon, and only in one case of the two Angles, the meridian and the horizon, may be the D. B. (2) The body or the angle to an aspect of whose position the directed body is moved is called tho stationary position (S. P.). The S. P. may be any one of the nine bodies and the two angles. (3) The aspect directed to is the aspect of direction, and its angular extent (A.E.) is measured from the stationary position towards D. B. (4) The point where the aspect directed to falls is termed the limit. limit may be to the anti-clockwise or clockwise side of the stationary position. The only stage of aspect recognised in directions is that of Complete or Pull Aspect, there being no direction to the Application or Separation of an Aspect. (5) The arc of direction (A. D.) is the arc through which the directed body is moved from its position at birth to form an aspect of the S.P. The arc of direction is measured from the directed body towards the S. P.
- 11. Classification of Directions—A direction has three features, (1) the natural phenomenon on which the direction rests, (2) the circle upon which the aspect extent of the direction and the arc of the direction are measured, and (3) the course of the direction. The classification of directions is based upon these features. (i) Directions are classified, in the main, into two groups, primary and secondary, according to the natural phenomenon underlying them. A pri-

mary direction is one which rests on the apparent diurnal rotation of the heavens: and a secondary direction is one which rests on the annual revolution of bodies. (ii) Primary directions are also divided into mundane and zodiacal ones, according as the aspect extent of direction is measured upon the equator or the ecliptic. Primary mundane directions are those in which the aspect extents of directions are measured upon the equatorial circle: and primary zodiacal directions are those in which the aspect extents of directions are measured upon the ecliptic circle. But secondary directions are all zodiacal, as the aspect extents of directions are always measured upon the ecliptic, (iii) A primary or secondary direction may be direct or converse, according as the course of direction is in consonance with or contrary to what obtains in nature. A body is said to move anti-clockwise in a circle when it moves against the hands of a watch, and clockwise when it moves with the hands of a watch. In primary mundane directions, a direction in which the D.B. is moved clockwise is said to be a direct direction, as the clockwise course of direction is in consonance with the natural apparent clockwise rotation of bodies in the heavens; and one in which the D₁B₂ is moved anti-clockwise is said to be a converse direction, as the anti-clockwise course of direction is opposed to what apparently obtains in nature. But in primary zodiacal directions and in secondary directions, one in which the D.B. is moved anti-clockwise is said to be a direct direction, since the anti-clockwise course of direction is in consonance with the anti-clockwise annual motion of bodies; and one in which the D.B. is moved clockwise is said to be a converse direction, since the clockwise course of direction is opposed to the natural anti-clockwise annual motion of bodies. All the above diverse classes of directions may be presented in the form of a pedigree as shown below. 1 propose to discuss the claims of these several groups of directions to be adopted in practice, taking each group in its proper place.

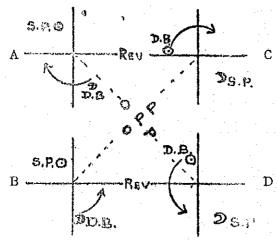

. 12. Notation of Directions—We should adopt a uniform method of noting directions, as it would avoid confusion. So, the symbol of the directed body is written first, next the symbol of the aspect of direction, and lastly the symbol of the stationary position, that is, the body or angle to whose aspect the direction

is made, e.g., \odot * (which means that the Sun is directed to the Sextile aspect of the Moon. And the word 'direct' or 'converse' along with the name of the class of directions, e.g., 'primary mundane', 'primary zodiacal' or 'secondary' are also mentioned.

- The Rules framed are Exhaustive, Comprehensive and Universal-In books on Directions, primary directions to fractional aspects, such as the quintile, are ignored, on the score that they are not of much significance, and those to aspects other than the conjunction and the opposition of the two Angles are usually omitted, as they are considered to be of little or no consequence. But they seem to be omitted especially because the formulæ and rules for calculating the arcs of directions become necessarily complicated and difficult. So I have framed rules under each class of directions, that would be applicable to all cases alike. Also, no attempt has been made in books to determine the very first primary direction after birth between all possible pairs of bodies, nor to work out the entire series of all the subsequent directions. On the other hand, directions are chosen at present by inspection and guess-work, and very meagre rules of no universal application are followed. But the rules that I have framed are exhaustive, comprehensive and of universal application, and so are scientific, and will help one to determine all directions to fractional as well integral aspects, from the very first moment after birth to any period of life.
- 14. Measurement of Time—The time when the effects of a direction are said to be realised in life, is always at a period later than the time when the direction will stand completed. Every four minutes after birth in primary directions, and every day after birth in secondary ones is made to measure to one year in life. Therefore, only such directions as could operate within the probable limits of life, such as 75 or 80 or 90 years, need be calculated.
- 16. Reverse and Opposite Directions—In books on Directions the expressions 'reverse direction' and 'opposite direction' are used rather indiscriminately. It would be better to restrict either of them to particular classes of directions which have no definite names. Two directions may be said to be the **reverse** of one another when they are both alike direct or converse with the directed body and the stationary position in one as the stationary position and the directed body in the other. And two directions may be said to be the **opposite** of one another when one is direct and the other converse with the directed body and the stationary position in one as the stationary position and the directed body in the other. That is, in each pair of both reverse and opposite directions, the D.B. and S.P. exchange their places, but while a pair of directions which are the reverse of one another are both alike direct or converse, a pair of directions which are the opposite of one another are contrary in their course, one being direct and the other

converse. For example, if the directions illustrated in Figure III are taken to be primary ones, then A and C are both direct primary ones which are the Reverse of one another, and B and D are both converse primary ones which are the Reverse of

- 16. Are Converse Directions Admissible?—To state the question in general terms, are directions of bodies contrary to what obtains in nature possible? Converse directions are unnatural; and so they are incontestably impossible. In

fact, they are repugnant to our scientific sense. However, we shall examine the two different arguments advanced in support of them. Firstly, converse directions are held to be pre-natal, that is, to have been completed before birth. is a only a specious reason. For, how can aspects completed when the native had no individuality bear any fruit in his life after he had acquired individuality by birth? In fact, birth is the very first moment in an individuals's life, and the positions of bodies and their aspects at birth are rightly held to be radical positions and aspects. Besides, the body directed to or the stationary position attains its position at birth only at birth, but not at a pre-natal moment. So, there can be no direction to a point at which the body directed to has not yet arrived. Secondly, converse directions are held to be what really obtains in nature, in that the real phenomenon is the anti-clockwise axial rotation of the Earth, but not the clockwise diurnal rotation of the heavens, and that, consequently, while bodies remain fixed in the heavens (but for their small annual motion), it is the Earth and so the mundane houses of bodies that sweep anti-clockwise past the bodies. Such indeed is the case. But as it is highly inconvenient to picture to ourselves what really obtains in nature, and to base all observations and calculations on the real nature of the phenomenon, it was elected to go by the apparent phenomenon of the clockwise diurnal rotation of the heavens, and to base all observations and calculations on such a view of affairs. Should we, notwithstanding the great strain that would be thrown on our powers of conception, choose to hold to the real phenomenon, then all methods of calculations should be reversed. For, ecliptic points will rise in the west and set in the east and, the semiarcs and cuspal distances of ecliptic points taken with no latitude, instead of those of celestial bodies taken with latitude will have to be calculated. we may adopt either phenomenon, the roal or the apparent. But not both. If we choose to go by the real phenomenon, then what are known now as direct directions will become impossible, and all methods of calculation should be thoroughly reversed, and such a course would render all observations highly impracticable. But if we decide to go by the apparent phenomenon, then what are known now as converse directions will become impossible, and all methods of calculation may remain as in vogue, and such a course would render all observations practicable. Hence, to calculate the arcs in converse directions without reversing the methods of calculation is flagrant outrage to reason. For these reasons, we ought to adopt the clockwise apparent diurnal rotation of the heavens and the anti-clockwise annual motion of bodies, and base all calculations upon them, and unreservedly rule out the practice of admitting both converse and direct directions, and what is worse, of calculating the arcs in converse directions without reversing the methods of calculation.

Contention I -Converse Directions are Inadmissible.

PÀRT I

PRIMARY DIRECTIONS

Primary Directions - Primary directions rest upon the apparent phenomenon of the clockwise diurnal rotation of the heavens, due to the anticlockwise axial rotation of the Earth. In consequence, celestial bodies appear to us to be moving clockwise in the heavens, every one at the same rate of motion as that of the Earth's axial rotation. The common rate of motion of all bodies is 360 equatorial degrees in 24 sidereal hours; and so one degree is rotated in 4 sidereal minutes. One equatorial degree or 4 sidereal minutes measures to one year of life. So all primary directions that could bear fruit during the first ninety years of an individual's life are completed within the first six sidereal hours (or 5 hours and 59 minutes of meantime) after birth. Hence, primary directions are all speedily formed and speedily dissolved within the first six sidereal hours of life. As one degree is rotated in 4 minutes, and as one degree measures to one year of life, so an error of about 4 minutes in the birth-time of an individual will not only shift the positions especially of fast moving bodies and points, such as the Moon and the Angles, but will also produce an error of about one year in the periods to which the directions measure. Consequently, the precise moment of birth should be carefully ascertained. Primary directions are so called because they are completed first in point of time after birth as compared with secondary directions. As a celestial body has both a mundane and a zodiacal position, two classes of primary directions are recognised at present, (1) those to the mundane aspects of the radical bodies and angles, called primary mundane directions, and (ii) those to the zodiacal aspects of the radical bodies and angles, called primary zodiacal directions. In primary mundane directions the arcs of directions are always measured upon the equator: while in primary zodiacal directions they are measured first upon the ecliptic and then referred to the equator.

LESSON II

PRIMARY MUNDANE DIRECTIONS

- Primary Mundane Directions-Primary mundane directions may be viewed to be direct or converse. Direct primary mundane directions are those in which the directed body is moved clockwise; and converse primary mundane directions are those in which the directed body is moved anti-clockwise. The path of direction is along the equator. Only a celestial body can be the directed body (D.B.), and only an angle or the radical position of a body can be the stationary position (S.P.). In primary mundane directions D.B. is directed to a mundane aspect of the position of only an angle or radical body. there are nine bodies and eleven positions, so we have 9 × 11 or 99 groups of primary mundane directions, with the same D.B. and S.P. in each group. And as there are twelve aspects-Conjunction, semi-sextile, semi-quintile, semisquare, Sextile, quintile, Square, Trine, sesqui-square, bi-quintile, quincunx and Opposition-leaving aside the Parallel, we obtain 99 × 12 or 1188 possible primary mundane directions. Since the heavens are perpetually rotating clockwise, every celestial body is dislocated clockwise [anti-clockwise] from its radical mundane position, that is, from I house to XII, XII to XI [XI house to XII. XII to I] and so on, reaching first the cusp of its own mundane house [the cusp of its next anti-clockwise house and next the cusps of its successive clockwise [anti-clockwise] houses till it arrives at its clockwise [anti-clockwise] horizon and rises or sets, and finally arrives at its own radical mundane position after 24 sidereal hours or one sidereal day. During this clockwise [anti-clockwise] rotation of the D.B., its clockwise [anti-clockwise] distance from every one of the eleven radical positions or the S.P.'s, continuously changes. The change may be an increase or decrease. Primary mundane directions may be calculated by adopting the mundane position as expressed by mundane distance or cuspal distance. The former will not be adopted as it will apply only to cases of conjunction and opposition, and the latter will be adopted as it will apply to cases of all aspects alike.
 - 19. Clockwise and Anti-clockwise Distances from D. B. to S. P—Two bodies on a circle will always have two arcs or distances between them. Each distance will be clockwise to only one of the two bodies, and anti-clockwise to the other. For example, in Figure IV the arcs A M B and B N A are the

[&]quot;The expressions within braces [] apply throughout to the cases of converse directions.

two distances between A and B, of which A M B is clockwise to A, and anti-clockwise to B; and B N A is clockwise to B, and anti-clockwise to A. To find the clockwise distance from a D.B. to an S.P., deduct the mundane position

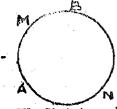

Fig. IV.-Clockwise and Ati-clockwise distances'

of othe S.P. from that of the D.B. (see Mathematical Astrology, Lesson VII, end of Art. 130). But the easiest method is to add (i) the C.D.F. of the D.B., (ii) the integral number of mundane houses running clockwise between the house of the D.B. and that of the S.P., and (iii) the C.D.B. of the S.P. moderated to the S.A. of D.B. at birth as follows, taking all arcs as they stood at birth:—

Birth S.A. of S.P.: its C.D.B.:: birth S.A. of D.B.: moderated C.D.B. of S.P.

Dictum I-Take all arcs as they stood at birth, in calculating distances.

For example, to obtain the mundane clockwise distance from Juptier, ix 13° 46′ to Saturn, VII 13° 46′, first moderate the C.D.B. of Saturn to the birth S.A. of Jupiter, the birth S.A. of Saturn being 81° 22′, its C.D.B. 13° 21′, and the birth S.A. of Jupiter, 58° 4′, proceed as follows:—

81° 22′; 13° 21′:: 58° 4′, : the C.D.B. of Saturn mod. to the birth S.A. of Jupiter. (A. C.) 9'65517 + 1'12979 + 0'49135 = 1'27631, T.P.L. of 9° 32′, (mod. C.D.B. of 4). Therefore, the mundane clockwise distance from Jupiter (D.B.) to Saturn (S.P.) is 13° 46+i+9° 32′, i.e., i 23° 18′.

Now, if the right ascensional degrees and minutes so obtained, is less than one house-space of the D.B. as it stood at birth, retain it as it is; but if it is greater, then deduct one house-space from the degrees and minutes obtained and add one to the number of integral houses. In the above example, 23° 18' is greater than 19° 21', one diurnal house-space of Jupiter, so deduct 19° 21' from 23° 18', and add one to i, and we obtain ii 3° 57' as the mundane clockwise distance from Jupiter to Saturn. Again, the clockwise distance from the Sun to Mercury is 19° 32' + xi + 16° 34', the C.D.B. of Mercury moderated to the Sun (see Sch. II), i.e., xi 36° 6'; and 19° 43' is one nocturnal house-space of Sun. So xi 36° 6' is equivalent to xii 16° 23' which is to be taken as the clockwise distance from the Sun to Mercury.

The anti-clockwise distance from a D.B. to an S.P. is readily had, being nothing but the explement of the clockwise distance, i.e., xii mundane houses minus the clockwise distance. But to find the anti-clockwise distance independently of the clockwise distance, reverse the above method, i.e., deduct the mundane position of the D.B. from that of the S.P. But as before, the easiest method is to add (i) the C.D.B. of the D.B., (ii) the integral number of mundane houses running anti-clockwise between the house of the D.B. and that of the S.P., and (iii) the

C.D.F. of the S.P. moderated to the birth S.A. of D.B. as follows:-

Birth S.A. of S.P.: its C.D.F.: birth S.A. of D.B.: moderated C.D.F. of S.P. For example, to obtain the mundane anti-clockwise distance from Jupiter (D.B.), ix 13° 46′, to Saturn (S.P.) VII 13° 46′, first moderate the C.D.F. of Saturn to the birth S.A. of Jupiter, the birth S.A. of Saturn being 81° 22′, its C.D.F. 13° 46′ and the birth S.A. of Jupiter, 58° 4′, proceed as follows:—

81° 22′: 13° 46′: 58° 4′: C.D.F. of Saturn mod. to the birth S.A. of Jupiter. (A.C.) 9'65517 + 1'11644 + 0'49135 = 1'26296, T.P.L. of 9° 49′, mod. C.D.F. of 4. Therefore, the mundane anti-clockwise distance from Jupiter to Saturn is 5° 35′ + ix + 9° 49′, i.e., ix 15° 24′; and as 15° 24′, the degrees and minutes obtained is less than 19° 21′, one diurnal house-space of Jupiter, we retain it as it is, and take the sum as the mundane anti-clockwise distance from Jupiter to Saturn. But if the degrees and minutes in the sum were greater than one appropriate house-space of the D.B., then deduct the latter from the former, and add one to the integral number of houses in the sum, as stated above. Again, the anti-clockwise distance from Neptune to Venus is 23° 10′ + xi + 23° 26′ the C.D.F. of Venus moderated to Neptune (see Sch. II), i.e., xi 46° 36′, and 28° 54′ is one nocturnal house-space of Neptune. So xi 46° 36′ is equivalent to xii 17° 42′ which becomes the anti-clockwise distance from Neptune to Venus. Therefore, we have

Rule I—The clockwise distance (Cl. D.) from D.B. to S.P. is C.D.F. of D.B.+ the number of clockwise mundane houses between D.B.'s and S.P.'s houses+the C.D.B. of S.P. moderated to S.A. of D.B. at birth: and the anti-clockwise distance (Acl. D) from D.B. to S.P. is C.D.B. of D.B.+ the number of anti-clockwise mundane houses between D.B.'s and S.P.'s houses+the C.D.F. of S.P. moderated to S.A. of D.B. at birth.

Rule II—When the degrees and minutes in the clockwise or the anticlockwise distance exceed one house-space of D.B. at birth, deduct the house space from the Cl. D. or Acl. D. and add one to the number of houses in the Cl. D. or Acl. D. If not, retain the Cl. D or Acl. D as it is,

Rule III—The moderation of C.D.B. [C.D.F.] of S.P. is as follows;—Birth S.A. of S.P.: its C.D.B. [C.D.F.]: birth S.A. of D.B.: mod. C.D.B. [C.D.F.]

20. The Shorter Distance between D.B. and S.P.—The clockwise distance is required in the calculations of the direct mundane directions, and the anticlockwise distance in those of the converse mundane directions. As all aspect extents are less than the extent of vi mundane houses, we always require arcs loss than vi houses. If either the clockwise distance or the anti-clockwise distance found as described in the previous article, is less than vi mundane houses, then it is also the shorter distance. But if it is greater than vi mundane houses, then rectify it by deducting it from xii mundane houses to obtain the shorter distance, which

may now be termed the rectified shorter distance. To facilitate subtraction of mundane distances, instead of xii mundane houses take xi mundane houses plus one house space of the D.B. at birth. For example, as shown in the previous article, the clockwise distance from Jupiter to Saturn being ii 3° 57′, it is taken, as it is, as the shorter distance. But the anti-clockwise distance from Jupiter to Saturn, as shown in the previous article, is ix 15° 24′, and it is greater than vi mundane houses, and so has to be rectified by deducting it from xii houses, ite., xi houses + 19° 21′, which latter is one diurnal house-space of Jupiter. Therefore, the rectified shorter distance from Jupiter to Saturn is xi 19° 21′—ix 15° 24′, i.e., ii 3° 57′. Hence, the shorter distance from a given body to a particular body is always identically the same, no matter if it has been derived from their clockwise or anti-clockwise distance: with this difference, that if a shorter distance has been obtained by the rectification of clockwise distance, then the same shorter distance will be obtained without the rectification of the corresponding anti-clockwise distance, and vice versa (see Schedule III).

Dictum II—When an arc exceeds a semi-circle or six houses, rectify it by deducting it from a full circle of twelve houses.

Again, when the clockwise or anti-clockwise distance exceeds xii houses, then cast off the full circle of xii houses and take only the remaining degrees and minutes as the shorter distance. In such a case the shorter distance is to be deemed to be an S.D. obtained with no rectification. Such a contingency arises when D.B. and S.P. are in the same house with the D.B. anti-clockwise [clockwise]. For example, the clockwise distance from the Sun to Mercury is xii 16° 23', so cast off the xii houses and take the remainder, 16° 23', as the shorter distance obtained with no rectification. And the anti-clockwise distance from Neptune to Venus is xii 17° 42', and casting off xii, the shorter distance with no rectification is 17° 42'. Therefore, we have

Rule IY—(a) When the Cl. D [Acl. D.] is not more than vi mundane houses, it is the shorter distance (S.D.): (b) when it is greater than vi but less than xii houses, xi houses + one house-space of D.B. at birth minus Cl. D. [Acl. D] is the rectified shorter distance (S.D.): and (c) when it exceeds xii houses, casting off xii houses, the balance is the shorter distance (S.D.) obtained with no rectification.

21. Increasing and Decreasing Series of Aspects of Direction—In primary mundane directions, when the clockwise [anti-clockwise] distance has not been rectified to obtain the shorter distance, the aspects continuously decrease, yielding a decreasing series of aspects, which may be termed Case I. And when the clockwise [anti-clockwise] distance has been rectified to obtain the shorter distance, they continuously increase, yielding an increasing series of aspects, which may be termed Case II. So, in Case I the aspect extent of the very first aspect of direction

will be just smaller than the clockwise [anti-clockwise] distance between D.B. and S.P., and the aspect extents of the subsequent aspects will go on decreasing till. Conjunction and then they will begin to increase. And in Case II, the aspect extent of the very first aspect of direction will be just greater than the clockwise [anti-clockwise] distance between D.B. and S.P., and the aspect extents of the subsequent aspects will go on increasing till Opposition and then they will begin to decrease. For example, iv 12° 30′, the S.D. from Mars to Neptune, direct, has been obtained with no rectification of the Cl.D., so the first aspect extent is just less than the S.D., iv 12° 30′, and so it is iv 0° 0′ or trine, and the subsequent aspects decrease, e.g., square, sextile and so on to Conjunction, and then increase again, iii 19° 2′, the S.D. from Mars to Jupiter, direct, has been obtained by the rectification of Cl.D., viii 1° 48′, so the first aspect extent is just greater than the S.D., iii 19° 2′, and it is iv 0° 0′ or trine, and the subsequent aspects increase, e.g., sesqui-square, quincunx, and Opposition, and then decrease. So, we have

Rule Y—(a) When the shorter distance has been obtained without rectification, the extent of the first aspect of direction is just Less than the S.D., and the extents of the subsequent aspects Decrease till Conjunction and then Increase: and (b) when the S.D. has been obtained with rectification, then the extent of the first aspect of direction is just Greater than the S.D., and the extents of the subsequent aspects Increase till Opposition, and then Decrease.

22. The Scale of the Aspect Extents of Directions—The extents of aspects taken should always be those of D.B. They may be either on the scale of D.B.'s diurnal or nocturnal S.A., according as the D.B. was above or below its horizon at birth. For example, in the direct directions of Jupiter which is above its horizon at birth, its S.D.A. is taken to start with and is changed for its S.N.A. when it sets in the west; again, in the direct directions of Mars which is below its horizon at birth, its S.N.A. is taken to start with and is changed for its S.D.A. when when it rises in the east. Therefore, we have

Rule VI—(a) The Aspect Extents are always to be taken on the scale of the Diurnal houses of D.B. so long as D.B. is Above its horizon; and (b) on the scale of the Nocturnal houses of D.B. so long as D.B. is Below its horizon.

But the aspect extents of the D.B. are always to be measured from the S.P. towards the D.B. along the S.D. For example, in the direct directions of Mars to Neptune, the extent of trine, the first aspect of direction and those of the subsequent aspects are all measured from Neptune towards Mars along the unrectified S.D., iv 12° 30'. Again, in the direct directions of Mars to Jupiter the extent of trine, the first aspect of direction, and those of the subsequent aspects are all measured from Jupiter towards Mars along the rectified S.D., iii 19° 2'. Therefore, we have

Rule VII—Aspect Extents are always to be measured from the S.P. towards the D.B. along the S.D. between them.

28. Arcs of Directions—The Arc of Direction (A.D.) is the arc through which D.B. is moved during a direction. In Case I the first arc of direction is equal to the shorter distance minus the first aspect extent: and in Case II it is equal to the first aspect extent minus the shorter distance. For example, in the direct directions of Mars to Neptune, the unrectified shorter distance being iv 12° 30′ and the first aspect extent, trine or iv 0° 0′, the first arc of direction is iv 12° 30′—iv 0° 0′, i.e., 12° 30′. Again, in those of Mars to Jupiter, the rectified shorter distance being iii 19° 2′, the first aspect extent, trine or iv 0° 0′, and one nocturnal house space of Mars being 20° 50′, the first arc of direction is iii 20° 50′—iii 19° 2′, that is, 1° 48′. Therefore, we have

Rule VIII—In Case I, the First A.D. = S.D.—the First A.E.: and in Case II, the First A.D. = the First A.E.—S.D.

When an aspect extent is an integral number of houses, deduct one from the number of houses, and add instead of it the degrees and minutes of one house-space of D.B. In both Cases I and II the A.D. of a subsequent direction always exceeds the previous A.D. by the difference between the previous aspect extent and the subsequent aspect extent. For example, the subsequent A.D.'s in the direct directions of Mars to Jupiter are:—

Mars sesqui-square Jupiter, 1° 48' + (iv 10° 24' - iv 0° 0') = 1° 48' + 10° 24' = 12° 12'. Mars bi-quintile Jupiter, 12° 12' + (iv 16° 39' - iv 10° 24') = 12° 12' + 6° 15' = 18° 27'. Mars quincunx Jupiter, 18° 27' + (v 0° 0' - iv 16° 39') = 18° 27' + 4° 10' = 22° 37'. Mars opposition Jupiter, 22° 37' + (vi 0° 0' - v 0° 0') = 22° 37' + 20° 50' = 43° 27'. Mars quincunx Jupiter, 43° 27' + (vi 0° 0' - v 0° 0') = 43° 27' + 20° 50' = 64° 17'. Mars bi-quintile Jupiter, 64° 17' + (v 0° 0' - iv 16° 39') = 64° 17' + 4° 10' = 68° 27'. Mars sesqui-square Jupiter, 68° 27' + (iv 16° 39' - iv 10° 24') = 68° 27' + 6° 15' = 74° 42'. Mars trine Jupiter, 74° 42' + (iv 10° 24' - iv 0° 0') = 74° 42' + 10° 24' = 85° 6'. Therefore, we have

Rule IX—(a) In Case I, Subsequent A. D. = the Previous A. D. + (the Previous A.E.—the Subsequent A.E.); and

- (b) in Case II, Subsequent Λ. D. = the Previous A. D. + (the Subsequent A.E.—Previous A.E.).
- 24. The Moderation of A.D. on D.B. Crossing its Horizon—Bodies below their horizon moved by the apparent diurnal rotation of the heavens, rise above their eastern [western] horizon (see Articles 18 and 22) during the very first or a subsequent direction, when the A.D. exceeds its eastern [western] horizontal distance. And bodies above their horizon set below their western [eastern] horizon during the very first or a subsequent direction when the A.D. exceeds its western

[eastern] horizontal distance. This is said to be the crossing of its horizon by a D.B. Therefore, the appropriate horizontal distance for bodies above their horizon is the western [eastern] horizontal distance, and for bodies below their horizon is the eastern [western] horizontal distance. For example, in direct directions, the appropriate horizontal distance (II.D.), for Saturn and Jupiter which are bottle above their horizon in George V's nativity, is the western horizontal distance (W.H.D.), and the appropriate II.D. for the other bodies which are all below their horizon is the eastern horizontal distance (E II.D.) Therefore, we have

Rule X—The appropriate H.D. (i) of a body above its horizon is its W.H.1.1. [E,H.D.], and (ii) of a body below its horizon is its E.H.D. [W.H.1)]

To obtain the E.II D of a body, its C.D.F [C.D.B.] is to be added to the total space of all the houses running clockwise [anti-clockwise] between its house and the eastern horizon. And to obtain the W.II.D. of a body, its C.D.B. [C.D.F.] is to be added to the total space of all the houses running clockwise [anti-clockwise] between its house and the western horizon. For example, the E.II D. of Mriss. direct, which is below its horizon, is 16° 38° + 4× 20° 49"7, i.e., 99° 57' Again, the W.H.D. of Jupiter, direct, which is above its horizon, is 13° 46' + 2× 19° 21"3, 1 c., 52° 29'. Therefore, we have

Rule XI—(i) The E H.D of a body=its C.D F. [C.D.B.] + the space of all houses running clockwise [anti-clockwise] from the cusp of its [of its next anti-clockwise] house to eastern horizon and (ii) the W.H.D. of a body—its C.D.F. [CDB] + the space of all the houses running clockwise [anti-clockwise] from the cusp of its [of its next anti-clockwise] house to western horizon. It will be evident that the spaces of all the houses will be on one and the same scale, diurnal or nocturnal, so long as A.D. does not exceed its appropriate II.1). But when A.D. exceeds the appropriate H.D of D.B., D.B. will cross its horizon and the scale will change from one to the other—in the case of bodies above their horizon, the change is from their S.D.A to S.N.A., and in those below their horizon, the change is from their S.N.A. to S.D.A. In such circumstances, the excess of A.D. over II.D. should be moderated to the new S.A. of D.B. The now S.A. of D.B. will be diurnal when D.B. rises in the east [west], and nocturnal when D.B. sets in the west [east]. The moderation of the excess of A.D. over the appropriate H.D. is carried on as follows—

Previous S.A. of D.B. Subsequent S.A. of D.B. Excess Moderated D.C. GHA. For example, to obtain the A.D. on Neptune crossing its horizon to form the direct square to Jupiter, Neptune being below and the direction direct, the appropriate H.D. is E.H.D. which is 5° 44′, the unrectified S.D. is in 14° 4′, unicl the first aspect extent is just less than in 14° 4′ which is square or in 0° 0′. Therefore, the first A.D. is equal to in 14° 4′—in 0° 0′, i.e., 14° 4′; and 14° 4′ is

greater than D.B.'s E.H.D. 5° 44′. So the excess of A.D. over H.D. is 8° 20′, which has to be moderated to the S.D.A. of Neptune, as it will be above its horizon after crossing. It is carried on as:—

86° 41': 93° 19' :: 8° 20': moderated excess.

(A.C.) 9'96797 (Sch. vi) + 1'33+37 = 1'30234, T.P.L. of 8° 58', the mod. excess. Again, in the direct direction, Saturn trine to the Sun, the A.D. obtained is 0° 27' + 13' 34', i.e., 14° 1' which exceeds 13° 46', the W.H.D. of Saturn, by 0° 15', which excess has to be moderated to 98° 38', the S.N.A. of Saturn whose S.D.A. is 81° 22', since Saturn is setting below its western horizon during the direction, as follows:—

81' 22': 98° 38': : 0° 15': moderated excess,

extents has to be changed from one to the other.

(A.C.) 9'916+2 (Sch. vi) + 2'85354 = 2'76996, T.P.L. of 0° 18', the mod. excess. Therefore, we have

Rule KII—The moderation of the excess of A.D. over H.D. is carried on.—Previous S.A. of D.B.: Subsequent S.A. of D.B.: Excess: Moderated Excess.

In such directions, the A.D. is equal to the sum of H.D. and the moderated excess. It should be borne in mind, that the previous A.D. is not used in the calculations when a body crosses its horizon. For example, the A.D. of Neptune direct square to Jupiter is its E.H.D. 5° 44′ + its moderated excess, 8° 58′, which is equal to 14° 42′; and the A.D. of Saturn direct trine to the Sun is, its W.H.D. 13° 46′ + its moderated excess, 0° 18′, which is equal to 14° 4′. Therefore, we have

Rule XIII—The A.D. when D.B. crosses its horizon—H.D.+moderated excess.

The subsequent A.D.'s are found as usual, only the scale of the aspect

25. Directions to the Angles—The above thirteen rules apply to the directions of bodies to the radical positions of Bodies. The rules have to be simplified to suit the cases of directions of bodies to the positions of the Angles, the (upper) Meridian and the (eastern) Horizon. (i) The S.P.'s, which are angles, have no C.D. to be moderated, so Rule I does not apply. (ii) For the same reason, the Cl. D. in direct directions to an Angle is equal to C.D.F. of D.B.+ the number of clockwise houses between D.B.'s house and the Angle, and the Acl. D. in converse directions, is equal to the C.D.B. of D.B.+ the number of anti-clockwise houses between D.B.'s house and the Angle, and so Rule II has to be modified as follows:—

The Cl. D, is equal to the C.D.F. of D.B. the number of clockwise houses from the cusp of the D.B.'s house and the Angle: and the Acl. D, is equal to the C.D.B. the number of anti-clockwise houses from the cusp of the D.B.'s next anti-clockwise house and the Angle.

(iii) Rule III will not apply, since in the clockwise and the anti-clockwise distance the odd right ascensional degrees and minutes are precisely the D.B.'s C.D.F. and C.D.B., and so will not exceed one house space of D.B. (iv) Rules XII and XIII also will not apply, for D.B. will arrive at the horizon itself with no excess, and so A.D. and H.D. will always come to coincide sooner or later, forming conjunction or opposition to either Angle and square to the other. Angle. So, while there is crossing and change in the scale of S.A.'s there will be no excess of A.D. over H.D. to be moderated. Therefore, in directions to either Angle only Rules IV to XI and the above modification of Rule II apply, and not the rest.

Determination of the A.D.'s in a Series of Primary Mundane 26. Directions—Now we are in a position to find the A.D.'s of a series of primary mundane directions and of any particular primary mundane direction. It would facilitate calculations, if we preliminarily prepare the following five schedules:-(1) The C.D.B.'s and C.D.F.'s of every S.P. moderated to the birth S.A. of each D.B., (Schedule II). (2) The S.D.'s, rectified or unrectified, from every D.B. to each S.P., derived from the clockwise and the anti-clockwise distance between them, (Schedule III). (3) The A.E.'s of every aspect of each D.B., both on the diurnal and the nocturnal scale, (Schedule IV). (4) The appropriate E.H.D. or W.H.D. of every D.B., (Schedule V). (5) The Ternary Proportional Logarithm of the ratio of the birth S.A. to the other S.A. of every D.B., (Schedule VI), It should be noted well that in utilising the Schedule of Aspect Extents, firstly, that the series of the aspects of directions change from the decreasing one to the increasing one on reaching Conjunction, and from the increasing one to the decreasing one on reaching Opposition; and secondly, that the scale of the aspect extents changes from the nocturnal to the diurnal on the D.B. rising above its horizon in the east [west], and from the diurnal to the nocturnal on D.B. setting below its horizon in the west east. The five Schedules, II to VI, have the inestimable advantage of enabling the calculator to steer clear of slips and errors, otherwise inevitable, for there is a rhythm about the succession and the flow of the figures in each schedule, when they are taken in particular orders, which the calculator on a slight reflection, will be able to readily realise and so to correct for himself easily all errors and slips that may creep into the schedules prepared.

We shall first calculate direct directions of bodies taken in their order at birth to (a) the two Angles, (b) the radical positions of Bodies, and next take up the converse directions of bodies in their order to (c) the two Angles, and (d) the radical positions of Bodies. In these calculations, as persons do not generally live beyond 90 years, we shall determine all A.D.'s whose measures do not exceed 90 degrees; but as a matter of fact, aspects for 75 years and A.D.'s of 75 degrees will do amply.

Schedule II-Birth C.D.B.'s and C.D.F.'s of S.P.'s Moderated.

The following eight problems illustrate all the principles and methods enunciated in Articles 18 to 26.

Problem 1—Find the A.D's. less than 90° of all the direct mundane directions of Venus to M. C.

```
? to M. C. E. H. D. =19° 41'.
```

Cl. D.= iii 19° 41' ... S.D. Unrect=iii 19° 41'. ... A. E.'s Decrease from S.D. till &.

D. B. is Below .. A. E.'s are Nocturnal till D. B. Rises.
.. 1st. A. E. is Nocturnal and just Less than S. D., i.e., iii 0° 0'=Square.

[1] ? CI M. C. A. D.=iii 19° 41'-iii 0 0=19° 41'.

Now A. D. equals H. D. .., D.B. Rises, and A.E's, become Diurnal.

[2] 9 Q M. C.
$$\Lambda$$
- D.=19° 41'+21° 26'=41° 7'.

[3]
$$9 \times M$$
, C. A. D.=41 $7+14$ $17=55$ 24.

Problem 2—Find the A. D's less than 90° of all the direct mundane directions of Mars to M. C.

.. A. E.'s. Increase from S. D. till 8.

D. B. is Below. .'. A. E.'s are Nocturnal till D. B. Rises.

., 1st. A.E. is Nocturnal and just Greater than S. D., i. e., iv 10° 24'= Sesqui-square, 딛

Problem 3-Find the Λ . D's less than 90° of all the direct mundane directions of Mercury to Horizon.

v to Hor. E. H. D.=27° 41'. Cl. D.=1 3° 49'. ∴ S. D. Unrect, =1 3° 49'

A. E's. Decrease from S. D. till &,

D. B. is Below. .. A. E's, are Nocturnal till D. B. Rises.

.. 1st A.E. is Nocturnal and just Less than S.D., i.e., i 0° 0' = Semi-sextile, &.

[1] V M Hor. A. D. == i 3° 49' - i 0° 0' == 3° 49'.

[2] § d Hor. .. 3 49+ 23 52 = 27 41.

A. D. equals H. D. .. D. B. Rises .. A. E's, become Diurnal

[3] V M Hor. A. D. = 27° 41'+36° 8' = 63° 49',

[4] 9 Z Hor. , =63 49 +18 4 =81 53,

Problem 4—Find the A. D's. less than 90° of all the direct mundane directions of Jupiter to Horizon.

u to Hor. W. 11. D. 52° 29'. Cl. D.=viii 13° 46'. S. D. Rect.=iii 5° 35'.

A. B.'s. Increase from S. D. till &,

```
D. B. is Above, .: A. E's, are Diurnal till D. B. sets,
```

.. Ist. A. E. is Diurnal and just Greater than S. D., i.e., iv 0° 0'=Trine, A.

```
[1] 2\mu \Delta Hor.—A. D.=iv 0° 0' or iii 19° 21'-iii 5° 35'=13° 46'.
```

[2]
$$\frac{13}{4}$$
 \square Hor,—... = 13 46 + 9 41 = 23 27.

[3]
$$24 \pm \text{Hor.}$$
 = 23, $27 + 45 + 49 = 29 + 16$.

[4]
$$\mu \times \text{Hor}_{-1} = 29 \ 16 + 3 \ 52 = 33 \ 8$$

[5]
$$\mu$$
 & Hsr.—, = 33 8 + 19 21 = 52 29.

Problem 5—Find the A. D's, less than 90° of all the direct mundane directions of Venus to Neptune.

? to
$$\Psi$$
 E. H. D.=19° 41', Cl. D=xi 19° 41'+23° 10' mod, to S. N. A. of D. B., ? .

86° 41': 23° 10': 72° 50': mod. C. D. B. of Ψ 0'57307+0'39294=0'96601, T. P. L. of 19° 28'.

D. B. is Below. .. A. E's. are Nocturnal till D. B. Rises.

.. 1st. A. E. is Noct, and just Loss than S. D., i.e., 0° 0'=Conjunction, d.

[1]
$$\theta$$
 θ Ψ Λ , $D_{r}=14^{\circ}\ 52'-0^{\circ}\ 0'=14^{\circ}\ 52'$,

[2]
$$\Psi$$
 Ψ Ψ $= 14 52 + 24 17 = (39° 9'),$

A. D. Exceeds H. D. by 19° 28' .. D. B. Rises .. Moderate, 72° 50' : 19° 28' : 107° 10' : mod. Excess. 9'83227+0'96601=0'79828, T. P. L. of 28° 38'.

[3]
$$?$$
 $\angle \Psi$, =48 19 +17 51 =66 10.

[4[
$$9 * \Psi$$
] = 66 10 + 17 52 = 84 2.

Problem 6-Find the A. D's less than 90° of all the direct mundane directions of Saturn to Neptune.

```
h to Ψ W. H. D.=13° 46'. Cl. D.=v 13° 46'+23° 10' mod, to S. D. A. of D.B., h.
```

86° 41′ ; 23° 10′ ; ; 81° 22′ ; mod, C, D, B, of Ψ 0.57307+0.34483=0.91790, T. P. L, of 21° 45′.

A. E's, Increase from S. D. till &.

D. B. is Above. .. A. E's, are Diurnal till D. B. sets.

:. 1st A. E's, is Diurnal and just Greater than S.D., i.e., vi 0°0' = Opposition, 8,

[2]
$$7 \times 4$$
 , 8 24+ 27 7=(35° 31'),

A. D. Exceeds H. D. by 21° 45' .', D. B. sets .'. Moderate. 81° 22' : 21° 45' : : 98° 38' : mod. Excess. 9916424-091790=083432, T. P. L. of 26° 22'.

 \therefore A, D. 13° 46' + 26° 22' = 40° 8'

[3]
$$h \pm \Psi$$
 , 40 8 + 6 34 = 46 42,

[4]
$$P = P = 10$$
 46 42 + 9 52 = 56 34.

[5]
$$h \triangle \Psi$$
 , 56 34 + 16 26 = 73 0.

Problem 7—Find the A. D's, less than 90° of all the direct mundane directions of Jupiter to the Sun.

```
# to @ W, H, D, 52° 29', Cl. D.=vi 13° 46'+0° 11' mod, to S. D. A. of D. B., 24,
        59° 9' ;0° 11; 58° 4'; mod. S. D. B. of ⊙
        2:50871+0:49135=3:00006, T. P. L. of 0° 11'.
        Cl. D. vi 13° 57', .. S. D. Rect. v 5° 24'.
       .. A. E's. Increase from S. D. till &.

Exercise 9-Prepare the schedule of the birth C.D.B,'s and C.D.F,'s of every S.P. ted to S.A. of each D.B. for the standard nativity,

Exercise 10 - Propare the schedule of the Clockwise and the Anti-clockwise Shorter ces from every D.B. to every S.P. for the standard nativity,

Exercise 11 - Propare the schedule of all the Aspect Extents, both on the diurnal and sturnal scale, of every D.B. for the standard nativity.

Exercise 12-Propare the schedule of the appropriate E.H.D. and W.H.D. of every : the standard nativity.

Exercise 13-Prepare the schedule of the T.P.L.'s of the ratios of the birth S.A. to ier S.A. of every D.B. for the standard nativity.

Exercise 14-Calculate the A.D.'s of all the direct directions of every Body to M.C. standard nativity,

Exercise 15 - Calculate the A.D.'s of all the direct directions of every Body to the i in the standard nativity,

Exercise 16 - Calculate the A.D.'s of all the direct directions of Mars to every S.P. standard nativity,

Exercise 17 - Calculate the A.D.'s of all the direct directions of Neptune to every the standard nativity,

Exercise 18 - Calculate the A.D.'s of all the direct directions of Jupiter to every S.P. standard nativity,

Exercise 19 - Calculate the A.D.'s of all the direct directions of Uranus to every S.P. in the standard nativity.

Exercise 20-Calculate the A.D.'s of all the direct directions of Venus to every S.P. in the standard nativity.

Exercise 21-Calculate the $\Lambda.D.$'s of all the direct directions of the Sun to every S.P. in the standard nativity.

Exercise 22 - Calculate the A.D.'s of all the direct directions of Moon to every S.P. in the standard nativity.

Exercise 23-Calculate the A.D.'s of all the direct directions of Salurn to every S.P. in the standard nativity.

Exercise 24-Calculate the A.D.'s of all the direct directions of Morcury to every S.P. in the standard nativity.

Exercise 25-Calculate the $\Lambda.D.$'s of all the converse directions of every Body to M.C. in the standard nativity.

Exercise 26-Calculate the A.D.'s of all the converse directions of every Body to the Horizon in the standard nativity.

Exercise 27 - Calculate the A.D.'s of all the converse directions of Mercury to every S.P. in the standard nativity.

Exercise 28 $^{\perp}$ Calculate the Λ .D.'s of all the converse directions of Saturn to every S.P. in the standard nativity.

Exercise 29-Calculate the A.D.'s of all the converse directions of Moon to every S.P. in the standard nativity.

Exercise 30-Calculate the A.D.'s of all the converse directions of the Sun to every S.P. in the standard nativity.

Exercise 31-Calculate the A.D.'s of all the converse directions of Venus to every S.P. in the standard nativity.

Exercise 32-Calculate the A.D.'s of all the converse directions of Uranus to every S.P. in the standard nativity.

Exercise 33-Calculate the A.D.'s of all the converse directions of Jupiter to every S.P. in the standary nativity.

Exercise 34-Calculate the A.D.'s of all the converse directions of Neptune to every S.P. in the standard nativity.

Exercise 35-Calculate the Λ ,D,'s of all the converse directions of Mars to every S.P. in the standard nativity.

27. Determination of the A. D. of a Body directed to a given Aspect—The first arc of direction after birth and then the subsequent arcs of direction may be determined in as rapid a succession as may be convenient, till the required aspect is reached, as described in Articles 19 to 25. But if one wants to calculate straight the arc of direction to any particular aspect, then he has to adopt the same rules with a few modifications. Firstly, find the clockwise [anti-clockwise] and the shorter distance as described in Articles 19 and 20. Secondly, take the A.E. on the scale of the S.A. of D.B. at birth (see Art. 22). The given aspect may be of the decreasing or increasing series, and the D.B. may be anti-clockwise or clockwise [clockwise or anti-clockwise] of the S.P. So, we have the following four cases:—

Case	A,	D.B. Ar	ıti-cloc kwis	e [Clockwise],	and	aspect of	Decreasing	series.
79	В,	33 Politica	11	17	· ,	,	Increasing a	series.
4 12,	,C,	,, Clo	ckwise [An	ti-clockwise].	, ,	,	Increasing	series
99	D,	33	12	23	٠,	,	Decreasing	series.

For example, in the series of direct directions of Mars to M.C. worked out in Problem 2, the aspects prior to opposition are of the increasing series and the very same aspects subsequent to opposition are of the decreasing series.

Thirdly, determine the A.D. with the aid of

Rule XIY—In Case A, A.D. = S.D. - A.E.
$$[xii - (S.D. + A.E.)]$$

B, A.D. = S.D. + A.E. $[A.E. - S.D.]$
C, A.D. = A.E. - S.D. $[S.D. + A.E.]$
D, A.D. = $xii - (S.D. + A.E.)$
 $[S.D. - A.E.]$

Next you should convert the A.D. obtained into its equivalent degrees and minutes by taking the integral number of houses in it on the scale of the S.A. of the D.B. at the commencement of the direction. Fourthly, find the appropriate H.D. of the D.B., that is, the E H.D. [W.H.D.] if it is below its horizon, and the W.H.D. [E.H.D.] if it is above its horizon (see Art. 24), Now, if the A.D. in degrees and minutes does not exceed the appropriate E.H.D. or W.H.D. of the D.B., then the A.D. obtained in degrees and minutes is the arc of direction. But if the A.D. exceeds the E.H.D. or W.H.D., then the excess of A.D. over E.H.D. or W.H.D. should-be moderated to the semi-arc of the D.B. other than the one at the beginning of the direction. In such a case, the sum of the E.H.D. or W.H.D. and the moderated excess is the A.D. in degrees and minutes.

Problem 9—Find the A.D. in the Direct direction of the Sun to its Decreasing mundane Quintile of the Meridian.

⊙ Q.M.C.--E.H.D. of ⊙ is 39° 15'.

Clockwise Unrect. S.D. between @ and M.C. is iv 19° 32'.

D.B. is below its horizon at birth.

.. Noct, A.E. of the Quintile of 1 is it 7° 53'.

D.B. is Anti-clockwise, and the Aspect is of Decreasing series,

Caso A. A.D. = S.D. -- A.E.

- "," D.B. is below its hor, and its one noct, house is 19° 43'
- .. A.D., ii 11° 39′=2×19 "43′+11° 39′=51° 5′.
- ... A.D. exceeds H.D. by 51° 5′-39° 15′, i.e., 11° 50′ the excess 11° 50′ should be moderated to S.D.A. of ②:--

59° 9': 120° 51' : 11° 50': moderated excess.

- 9'68971 (Sch. VI) +1.18217 = 0'81788, T.P.L. of 24° 11'.
- .'. A.D. = 39° 15' + 24° 11' = 63° 26'.

Problem 10—Find the A.D. in the Direct direction of Uranus to its Increasing mundane Semi-square of Mercury.

W 4 F.H.D. of Ut is 54° 26'.

Clockwise Unrect. S.D. between H and ? is i 13° 32', D.B. is below its horizon at birth.

.. Noct. A.E. of the Semi-square of Ht is i 9° 28'...

D.B. is Anti-clockwise, and the aspect is of Decreasing series.

Case B. A.D. = S.D. + A.E.

- .: =i 13° 32'+i 9° 28'=ii 23° 0'.
- . D.B. is below its hor, and its one noct. house is 18° 56'.
- \therefore A.D., ii 23° 0′ = 2 x 18° 56′ + 23° 0′ = 60° 52′.
- : A.D. exceeds H.D. by 60° 52′ 54° 26′, i.e., 6° 26′, the excess, 6° 26′, should be moderated to S.D.A. of #:-

56° 48° 123° 12′ 16° 26′; moderated excess. 9'66374+1'44684=1'11058, T.P.L. of 13° 57′.

Y. A.D. = 54° 26' + 13° 57' = 68° 23'.

Problem 11—Find the D.B. in the Direct direction of Neptune to its Increasing mundane Quintile of Mercury.

Ψ Q & EHD of Ψ is 5° 44'.

Clockwise Rect. S.D. between Ψ and ¥ is 0 27° 48'.

D.B. is below its horizon at birth,

... Noct. A.E. of the Quintile of Ψ is ii I1° 34'.

D.B. is Clockwise, and the Aspect is of Increasing series,

Case C. A,D,=A,E,-S,D,

, = ii 11° 34'-0 27° 48'=i 40° 28'-0 27° 48', for Ψ is below its hor., and its one noct, house is 28° 54'.

.. A.D.=i 12° 40'.

For the same reason, A.D. i I2° 40' = 28° 54' + 12° 40' = 41° 34'.

... A.D. exceeds H.D. by 41° 34′ -5° 44′, i.e., 35° 50′, the excess, 35° 50′, should be moderated to S.D.A. of Ψ:—

86° 41′ : 93° 19′ : : 35° 50′ : moderated excess. 9'96797 + 0'70099 = 0.66896, T.P.L. of 38° 35′.

 \therefore A.D. = 5° 44' + 38° 35' = 44° 19'.

Problem 12.—Find the D.B. in the Direct direction of the Sun to its Decreasing mundane Sesqui-square of Saturn.

□ h—E-H.D. of ⊙ is 39° 15′.

Clockwise Rect. S.D. between @ and h is iv 10° 12'.

D.B. is below its horizon at birth.

.. Noct. A.E. of the Sesqui-square of O is iv 9° 51'.

D.B. is Clockwise, and the Aspect is of Decreasing series.

Case D. A.D. = xii - (S.D. + A.E.)

, =xii-(iv 10° 12'+iv 9° 51')=xi 19° 43'—ix 0° 20', for ⊙ is below its hor, and its one noct house is 19° 43'.

- \therefore A.D = ii 19° 23′.
- .. For the same reason, A.D., ii $19^{\circ} 23' = 2 \times 19^{\circ} 43' + 19^{\circ} 23' = 58^{\circ} 49'$
- .. A.D. exceeds H.D. by 58° 49′—39° 15′, i.e., 19° 34′, the excess, 19° 34′ should be moderated to S.D.A. of ⊙ :—

59° 9′ : 120° 51′ : 19° 34′ : moderated excess, 9′68971 + 0′96376 = 0′65347, T.P.L. of 39° 59′,

.. A.D. = 39° 15′+38° 59′=79° 14′.

Exercise 36-Find the A.D. in the Direct direction of Mars to the Decreasing mundane Conjunction of Saturn in the standard nativity.

Exercise 37—Find the A.D. in the Direct direction of Jupiter to the Increasing mundane Sextile of itself, in the standard nativity.

Exercise 38-Find the A.D. in the Direct direction of the Sun to the Decreasing mundane Square of Uranus in the standard nativity.

Determination of the Mundane Aspect of a given A. D.—The determination of an aspect given the arc, that is, the determination of the aspect whose influence will be felt at a particular age in an individual's life, is just the converse of the problem described in the previous article. As before, find the appropriate horizontal distance of the directed body, and the shorter distance rectified or unrectified, between the directed body and the stationary position. Now, if the A.D. is given in years and months convert them into degrees and minutes at the rate of one degree per year; and if it is given in ordinal number of years, e.g., the 58th year then take the mid-point, i.e., 57th years and convert it into degrees and minutes. But if the A.D. is given in degrees and minutes take them as they are. After converting, if necessary, the given arc of direction, into degrees and minutes, we should see if it exceeds the appropriate horizontal distance of the D.B. If it does not exceed, take it as it is; and if it exceeds, inversely moderate the excess to the semi-arc of the directed body at birth, for the excess obtained is on the scale of its other semi-arc. Then take the sum of the horizontal distance and the inversely moderated excess as the given A.D. Next, convert the new A.D. found in degrees and minutes into its equivalent houses, degrees and minutes, taken on the scale of the S.A. of the directed body at There are the same four cases as those stated in Article 27; and the A.E. on the birth scale is determined with the aid of

```
Rule XY-In Case A, A.E. = S.D. - A.D.
                                                  [xii - (S.D. + A.D.)]
              Case B, A.E. = A.D. - S.D.
                                                  [A.D. + S.D.]
              Case C, A.E. = A.D. + S.D.
                                                  [A.D. - S.D.]
              Case D, A.E. = xii - (S.D. + A.D.)
                                                  [S.D. - A.D.]
```

Now that A.E. is known, the corresponding Aspect may be read from Schedule IV.

Problem 13.—Find the Decreasing Direct mundane aspect of the Sun to the Moridian, relating to the 64th year in George V's life.

Given 64th year is approximately equal to A.D. 63° 30'.

E.H.D. of @ is 39° 15'.

Clockwise Unrect. S.D. between O and M.C. is iv 19° 32'.

'.' Given A.D., 63° 30', exceeds H.D. by 24° 15', the excess should be moderated inversely as follows:—

120° 51 ; 59° 9' ; ; 24° 15' ; moderated excess. 1'31029+0'87056=1'18085, T.P.L. of 11° 51',

A.D. becomes 39° 15'+11° 51'=51° 7, which should be taken as nocturnal, for the excess has been moderated to S.N.A. of O.

A.D., 51° 7'=2×19° 43'+11° 41', for one noct, house of O is 19° 43',

A.D. = ii 11° 41′.

D.B. is Anti-clockwise, and the Aspect is of the Decreasing series, Case A., A.E. = S.D. - A.D.

;; =iv 19° 32'-ii 11° 41'=ii 7° 51' (Noct.)

" = Quintile of O.

The required Aspect is O Q M.C.

Problem 14.—Find the Increasing Direct mundane aspect of Uranus to Mercury, relating to the 69th year in George V's life.

Given 69th year is approximately equal to A.D. 68° 30'.

E.H.D. of H is 54° 26'.

Clockwise Unrect. S.D. between Ill and B is i 13° 32',

".' Given A.D. 68° 30', exceeds H.D. by 14° 4', the excess should be moderated inversely as follows:—

123° 12' : 56° 48' : : 14° 4' : moderated excess.

0'33626+1'10708=1'44334, T.P.L. of 6° 29'.

- .. A.D. becomes 54° 26'+6° 29'=60° 55', which should be taken as nocturnal, for the excess has been moderated to S.N.A. of III.
- .. A.D., 60° $55' = 3 \times 18^{\circ}$ $56' + 4^{\circ}$ 7' = iii 4° 7', for one noct, house of % is 18° 56'.
- .'. A.D. = iii 4° 7',

D.B. is Anti-clockwise, and the Aspect is of the Increasing series.

Case B., A.E. = A.D. - S.D.

- .. = iii 4° 7'-i 13° 32'=i 9° 31' (Noct.), for one house of 11 in 18° 56'.
- " = Semi-square of III;
- The required Aspect is III 2 8.

Problem 15.—Find the Increasing Direct mundane aspect of Neptune to Mercury, relating to the 45th year in George V's life,

Given 45th year is approximately equal to A.D. 44° 30',

E.H.D. of Ψ is 5° 44'.

Clockwise Rect. S. D. between W and W is 0 27° 48'.

Given A.D. 44° 30', exceeds H.D. by 38° 46', the excess should be moderated inversely as follows:—

93° 19' : 86° 41' : : 38° 46' : moderated excess.

0.03203+0.66681=0.69884 T.P.L. of 36° 1'.

- ... A.D. becomes 5° 44'+36° 1'=41° 45', which should be taken as nocturnal, for the excess has been moderated to S.N.A. of ψ
- .. A.D., $41^{\circ} 45' = 1 \times 28^{\circ} 54'' + 12^{\circ} 51'$, for one noot, house of Ψ is $28^{\circ} 54'$,
- .. A.D. = i 12° 51'.

D.B. is Clockwise, and the Aspect is of the Increasing series,

Case C., A.E. = A.D. + S.D.

- " = i 12° 51'+0 27° 48'=ii 11° 45' (Noot.), for one house of Ψ is 28° 54' = Quintile of Ψ ,
- .. The required aspect is Ψ Q Ş

Problem 16.—Find the Decreasing Direct mundane aspect of the Sun to Saturn, relating to the 80th year in George V's life.

Given 80th year is approximately equal to A.D. 79° 30'.

E.H.D, of O is 39° 15'.

Clockwise Rect. S.D. between O and h is iv 10° 12'.

Given A.D. 79° 30' exceeds H.D. by 40° 15', the excess should be moderated inversely as follows:—

120° 51'; 59° 9'; : 40° 15'; moderated excess.

9'31029+0'65051=0'96080, T.P.L. of 19° 42',

- . A.D. becomes 39° 15'+19° 42'=58° 57' which should be taken as nocturnal, for the excess has been moderated to S.N.A. of \odot .
- ... A.D., 58° $57' = 2 \times 19^{\circ}$ $43' + 19^{\circ}$ 31', for one nect, house of \odot is 19° 43',
- .. A.D. = ii 19° 31', $\sqrt{}$

D.B. is Clockwise and the Aspect is of the Decreasing series,

Case D., $\Lambda_{\cdot}E_{\cdot}=xii-(S.D.+\Lambda_{\cdot}D.)$

- " = xii (iv 10° 12' + ii 19° 31') = xi 19° 43' vii 10° 0'.
 " = iv 9° 43' (Noct.), for one house of \odot is 19° 43',
- = Semi-square of ⊙.
 ∴ The required aspect is ⊙ ∠ ♭.

To calculate the A.D.'s in isolated cases, it will do to prepare instead of Schedule II, a schedule of the ternary proportional logarithms of the ratios of the birth S.A.'s of S.P.'s to their C.D.B.'s to be used in direct directions, and of their C.D.F.'s to be used in converse directions, and to note also the T.P.L. of the S. A.'s of D.B.'s at birth,

SCHEDULE-VII.

T.P.L.'s of the Ratio, S.A. of S.P.: C.D.B. or C.D.E. of S.P..

S.P.'s in their order.	T.P.L. of S.A. of S.P. at birth: C.D.B. of S.P.	T.P.L. of S.A. of S.P. at birth: C.D.F. of S.P.	T,P.L. of S.A. of D.B. at birth.

Exercise 39-What is the Increasing Direct mundane aspect of Venus to Sun, that operates in the 68th year in the standard nativity.

Exercise 40—What is the Decreasing Direct mundane aspect of Saturn to Jupiter, that operates in the 37th year in the standard nativity.

Exercise 41—What is the Increasing Direct mundane aspect of Neptune to Uranus, that operates in the 72nd year in the standard nativity.

29. Relation between primary mundane directions to the Meridian and those to the Horizon.—It will be seen that the A.D.'s of a D.B. to mundane aspects of the Meridian and to those of the Horizon are identically the same, and the corresponding aspects though different in name bear a definite relation to one another. The relations may be ascertained from the schedule below.

Schedule VIII-The Relation between the Directions to the two Angles.

To one	•	To the other	To one		To the other		To one		To t	he	othe	r
ડ	***	Ö	*	•••	T or L	•••	Ę		4	or	G	
		Δ or *			8 or d							
4	***	Q or Z	Δ.	***	L or T	***	S.	•	c)			

So if the A.D. of an aspect, other than the quintile and the biquintile, of a body to one of the Angles is known, we can readily state the aspect of the body to the other angle, having the same A.D. with the aid of

Rule XVI.—When the mundane aspect of a body to an Angle is given, to obtain the mundane aspects of the body to the other Angle, to the given mundane aspect of a body to an Angle add three houses, and if necessary, cast off 6 houses from the sum: and also deduct the given mundane aspect from 9 houses, and if necessary, cast off 6 houses from the remainder. The reader may verify the rule by comparing the A.D.'s in the following directions to the two Angles:—

```
Dir. to Merid, or Dir. to Hor,
                                 Arc.
                                         Dir. to Merid, or Dir. to Hor.
                                                                           Arc.

```

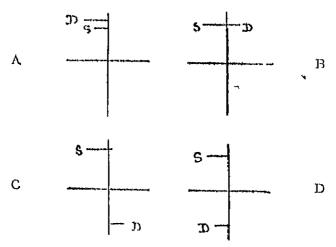

Since the A.D.'s in a corresponding pair of directions to the two Angles are identically the same, except in regard to the Quintile series, those to M.C. alone may be calculated. As the two of a pair are inseparables their combined effect may be read in regard to the directions to M.C.

Contention II.—The Arcs of Directions to the Horizon need not be calculated.

LESSON III

MUNDANE PARALLEL

- 30. Primary Directions to the Mundane Parallel.—Two points are in mundane parallel when they are one on each side of the same meridional half or on the same side of opposite meridional halves, with the ratios between their semi-arcs and their distances from the same or opposite meridional half equal. These two kinds of parallels constitute two different types, as will be seen presently. In directions to parallel as in those to aspects of the position of bodies, only one body is moved to the parallel of its own position at birth or to that of another body at birth, but never to the parallel of an angle. The D.B. may be moved clockwise resulting in direct mundane parallels or anti-clockwise resulting in converse mundane parallels.
- 31. The Different Types of Mundane Parallels.—The definition of a mundane parallel given in Article 30, admits of four patterns of mundane parallels, shown in Figure V.

- Fig. V.-A. D.B. and S.P. are on the same side of meridian and horizon.
 - B. D.B. and S.P. are on the opposite sides of meridian and the same side of horizon.
 - C. D.B. and S.P. are on the opposite sides of the meridian and hor.
 - D. D.B. and S.P. are on the same sides of meridian and opposite sides of horizon.

Figure V—A is nothing but mundane conjunction, and Figure V—C. is nothing but mundane opposition: so these two patterns of mundane parallel should be ruled out, as otherwise one and the same aspect will receive two different names, and so will tend to convey different significance. Figure V—B. is indisputably a mundane parallel upon the meridian, and Figure V—D. may be taken to be a mundane parallel but it is evidently more a parallel upon the horizon than upon the meridian. Though some writers do question these parallels upon the horizon. I shall discuss their calculation as well, and leave it to the reader to adopt them or not. I shall speak of the former as Mundane Parallels of Type No. 1, and of the latter as Mundane Parallels of Type No. 2. Therefore, we have.

Rule XVII.—Mundane parallels of Type 1 are formed with the D.I3. and the S.P. on opposite sides of the meridian but on the same side of the horizon: and those of Type 2 are formed with the D.B. and the S.P. on the same side of the meridian but on opposite sides of the horizon.

In other words those of Type 1 are upon the same meridional half, and those of Type 2 are upon opposite meridional halves, shutting out what really are conjunctions and oppositions.

- of the nine celestial bodies is the D.B., and the position at birth of one of the nine celestial bodies is the S.P. At birth only a very few or no pairs of bodies are in mundane parallel. But the diurnal rotation of the heavens shifts bodies causing them to move clockwise through the mundane quadrants in succession. During this clockwise rotation, a D.B. is brought to occupy a distance proportionate to its semi-arc, either from the other side of the same meridlonal half to that of S.P., or from the same side of the opposite meridional half as that of S.P. Again, in direct mundane parallels the arc of direction is the clockwise angle from the D.B. to its position at the parallel: and in converse mundane parallels, it is the anti-clockwise angle from the D.B. to its position at parallel.
- 88. The Meridional Half of Parallel.—Since the position of a body at birth is fixed, and since the D.B. should come to parallel either on the same meridional half as the stationary position or on the opposite meridional half to it. therefore, the meridional half of parallel (M.H.P.) will be either on the same side of the horizon as the stationary position as in Type 1 or on the opposite side of the horizon as in Type 2. Therefore, we have,

Rule XVIII.—The meridional half of parallel in Type I is the one on the same side of the horizon as the stationary position at birth: and in Type 2 is the one on the side of the horizon opposite to that occupied by the S.P. at birth.

84. The Meridianal Distance of D.B.—We have seen in Article 32, that the A.D. is measured from the position of the D.B. at birth to the position of

D.B. at parallel, and both the positions are expressed in distance from the meridian of parallel. So, we have to take (i) the M.D. of D.B. at birth, and (ii) the M.D. of D.B. at parallel, in both cases from the M.H.P. In Type 1 the M.D. of D.B. at birth is taken similar, diurnal or nocturnal, to the S.P. And the M.D., diurnal or nocturnal, of S.P. is taken according as it is above or below its horizon; for the M.H.P. is similar to S.P. at birth. In Type 2 the M.D. of D.B. at birth is taken opposite to the S.P. at birth, for the M.H.P. is opposite to the S.P. So we have,

Rule XIX.—In Type 1 the birth M.D. of D.B. is to be taken similar to that of S.P. at birth, and in Type 2 it is to be taken opposite to that of S.P. at birth. It should be evident that the first or birth M.D. of D.B., to be spoken of hereafter as merely the M.D. of D.B., is similar to the M.H.P. in both the Types.

86. Moderation of the Meridional Distance of the Stationary Position.—In Article 30 it was stated that in mundane parallels, the ratio between the S.A. and the M.D. of D.B. should be equal to that between the S.A. and the M.D. of S.P. To find the meridional distance of the D.B. at which the two ratios would be equal, we have to moderate the meridional distance of the S.P. from the meridional half of parallel to the semi-arc of the D.B. at parallel. So we have to find the S.A. of D.B. at parallel, and to moderate the birth M.D. of S.P. to it. In Type 1, the M.H.P. is similar to the S.P. at birth, so S.A. of D.B. is to be taken similar to S.A. of S.P. at birth, e.g., both are to be taken alike, diurnal or nocturnal. In Type 2, M.H.P. is opposite to S.P. at birth, so S.A. of D.B. is to be taken opposite to S.A. of S.P. at birth, which is the S.A. of D.B. at parallel. So we have,

Rule XX.—In Type I, the S.A. of D.B. at parallel is taken similar to S.A. of S.P. at birth, and in Type 2, it is taken opposite to S.A. of S.P. at birth. Now the birth M.D. of S.P. is to be moderated to the S.A. of D.B. at parallel:—Birth S.A. of S.P. Birth M.D. of S.P.: S.A. of D.B. at parallel: mod. M.D. of S.P. For example, in the direct mundane parallel, Type 1, of Neptune to Jupiter, S.P. is diurnal, so the M.H.P. and the S.A. of D.B. are both diurnal. The S.A. of S.P. is 58° 4′, its M.D. 5° 35′, S.D.A. of Neptune is 93° 19′. So, moderate as:—

58° 4′: 5° 35′: 93° 19′: moderated M.D. of S.P.
1'01703+0'28531=1'30234, T.P.L. of 8° 58′, which is the moderated M.D. of S.P.
Again in the direct mundane parallel, Type 2, of Saturn to Jupiter, S.P. is diurnal, so the M.H.P. and S.A. of D.B. are nocturnal. The S.A. of S.P. at birth is 58° 4′ and its M.D. 5" 35′, and S.N.A. of Saturn is 98° 38′. So moderate as:—

58° 4': 5° 35': : 98° 38': moderated M.D. of S.P. 1'01700 + 0'26125 - 1'27828, T.P.L. of 9° 29'. Therefore, we have,

Rule XXI.—Moderate birth M.D. of S.P.:

Birth S.A. of S.P.: Birth M.D. of S.P.: S.A. of D.B. at II: mod. M.D. of S.P.

- 36. The Arc of Direction.—It was stated in Article 34 that to find the A.D. we have to take (i) the M.D. of D.B. at birth and (ii) the M.D. of D.B. at parallel which is nothing but the moderated M.D. of S.P. discussed in Article 35. Let us now proceed to determine the A.D. The various possible permutations of the birth positions of D.B.'s and those of S.P.'s in Type 1, may be grouped under four heads;—
 - (i) when D.B. crosses the M.H.P. (see Fig. VI A and VII A);
 - (ii) when D.B. crosses the M.H. opposite to M.H.P. (see Fig. VI B and VII B);
 - (iii) when D.B. does not cross the M.H.P. (see Fig. VI C & D, and VII C & D);
 - (iv) when D.B. crosses both M. H's. (see Fig. VI E & F and VII E & F).

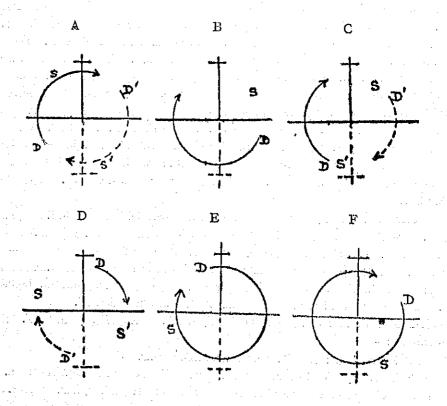

Fig. VI-Direct Mundane Parallels of Type 1..

In each figure the M.H.P. is indicated by a straight line and the M.H. opposite to

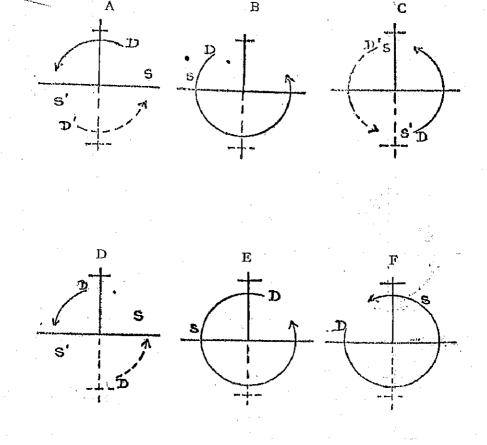

Fig. VIII-Converse Mundane Parallels of Type 1,

In each figure the M.H.P. is indicated by a straight line, and the M.H. opposite to the M.H.P. by a dotted line,

And the various possible permutations of the birth positions of D.B. and S.P. in Type 2, may be grouped under similar four heads:—

- (i) When D.B. crosses the M.H.P. (see Fig. VIII A and IX A.)
- (ii) When D.B. crosses the M.H. opposite to M.H.P. (see Fig. VIII B and IX B.)
- (iii) When D.B. does not cross the M.H.P. (see Fig. VIII C & D and IX C and D.)
- (iv) When D.B. crosses both M.H.'s (see Fig. VIII E & F and IX E & F.)

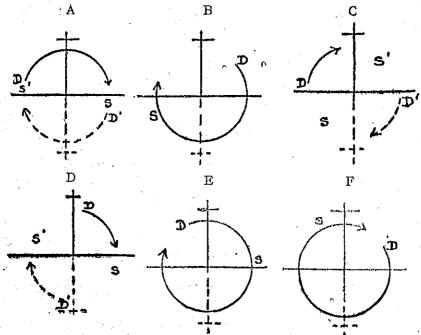

Fig. VIII-Direct Mundane Parallels of Type 2.—The lines as in Figures VI and VII.

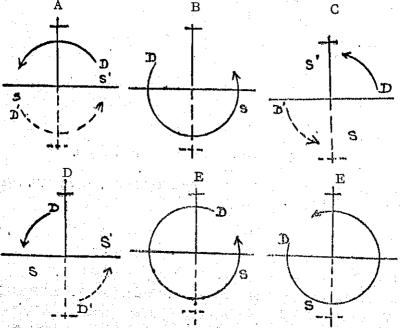

Fig. IX-Gonverse Mundane Parallels of Type 2.—The lines as in Figures VI and VII.

The arcs of direction, i.e., the angular measurements of the arcs running clockwise [anti-clockwise] from D.B at birth to D.B. at parallel, in these several cases of both direct and converse mundane parallels of both Types 1 and 2, are found with the aid of the following formula:—

Type 1. Direct and Converse, and Type 2 Direct and Converse.

- (1) A.D. = Birth M.D. of D.B. from M.H.P. + moderated M.D. of S.P.
- (2) A.D. = 360° (Birth M.D. of D.B. from M.H.P. + mod. M.D. of S.P.)
- (3) A.D. = Birth M.D. of D.B. from M.H.P. ~ moderated M.D. of S.P.
- (4) A.D. = 360° (Birth M.D. of D.B. from M.H.P. ~ moderated M.D. of S.P.)

As (birth M.D. of D.B. from M.H.P.+moderated M.D. of S.P.) and, much more therefore, (birth M.D. of D.B. from M.H.P. ~ moderated M.D. of S.P.) will at the most be not more than 270°; therefore, 360° – (birth M.D. of D.B. from M.H.P.+ moderated M.D. of S.P.) and 360° – (birth M.D. of D.B. from M.H.P. ~ moderated M.D. of S.P.) will never be less than 90°, and so the parallels of groups (2) and (4) will not fall within the span of 90 years. Therefore, parallels falling under groups (2) and (4) may be omitted from calculations. And so both direct and converse mundane parallels of either Type 1 or Type 2 may be sorted under groups 1 and 3, which shall be spoken of as Cases (i) and (ii) of both Types 1 and 2. Therefore, we have

Rule XXII.—In Type 1 and Type 2 of both direct and converse mundane parallels of Case (i), where D.B. crosses the M.H.P.,

A.D. = Birth M.D. of D.B. from M.H.P. + moderated M.D. of S.P.

And in Type 1 and Type 2, of both direct and converse mundane parallels of Case (ii), where D.B. does not cross the M.H.P.;

A.D. = Birth M.D. of D.B. from M.H.P. ~ moderated M.D. of S.P.

Problem 17—Find the A.D. in the direct mundane parallel, Type 1, of Moon to Mars.

The M.H.P. is the lower meridienal half,

D, the D.B., crosses the M.H.P.

The birth M.D. of D from L.M.H. is 89' 7, and its S.N.A. is 93° 20'.

The birth M.D. of & from L.M.H., is 37° 28', and its S.N.A. is 62° 29',

Therefore, moderate as follows :-

62° 29' : 37° 28' : : 93° 20' : moderated M.D. of d.

0'22212+0'28524=0'50736 ,T.P.L. of 55° 58'.

Caso (i) A.D. = 80° 7' + 55° 58' = 145° 5' (lato).

Problem 18—Find the A.D. in the direct mundane parallel, Type 1, of Neptune to Jupiter.

The M.H.P. is the upper meridional half. Ψ , the D.B., does not cross the M.H.P. The birth M.D. of Ψ from U.M.H. is 99° 3′, and its S.D.A. is 93° 19′.

The birth M.D. of 4 from U.M.H. is 5° 35' and its S.D.A. is 58° 4'.

The sign ~ means deduct the less term from the greater.

.. 58° 4′; 5° 35′; 93° 9′; moderated M.D. of 4. 1'01703+0'28531=1'30234, T.P.L. of 8° 58.′

Case (ii) A.D.=99° 3'-8° 58'=96° 5' (late).

Problem 19—Find the A.D. in the direct mundane parallel, Type 1, of Uranus to Mars.

The M.H.P. is the lower meridional half. #1, the D.B., does not cross the M.H.P. The birth M.D. of #1 from L.M.H. is 2° 22' and its S.N.A. is 56' 48'.

The birth M.D. of & from L.M.H. is 37° 28', and its S.N.A. is 62° 29'.

.: 62° 29' : 37° 28' : : 56° 48' : moderated M.D. of &.

Case (ii) A,D, = 34° 4' - 2° 22' = 31° 42'.

To calculate the A.D.'s of isolated mundane parallels, it will do to prepare a schedule of the ternary proportional logarithms of the ratios of the S.A. of S.P.'s at birth to their birth M.D.'s, and to note the T.P.L.'s of S.D.A.'s and S.N.A.'s of D.B.'s.

Schedule IX-The T.P.L.'s of S.A. of S.P: M.D. of S.P.

Exercise 32-Find the Λ .D. in the direct mundane parallel, Type 1, of Sun to Venus in the standard nativity.

Exercise 33-Find the A.D. in the direct mundane parallel, Type 1, of Mars to Jupiter in the standard nativity.

Exercise 34-Find the A.D. in the direct mundame parallel, Type 2, of Neptune to Sun in the standard nativity.

Exercise 35 - Find the A.D. in the converse mundane parallel, Type 1, of Neptune to itself in the standard nativity.

Exercise 36-Find the A.D. in the converse mundane parallel, Type 1, of Uranus to Saturn in the standard nativity.

Exercise 37-Find the A.D. in the converse mundane parallel, Type 2, of Moon to Mars in the standard nativity.

87. Determination of A.D.'s in the mundane parallels of all bodies to different S.P.'s .- In the primary directions of bodies to mundane aspects of angles and bodies we may take the bodies one by one as the directed body, as D.B.'s play the leading part. But in the primary directions of all bodies to the mundane paralles of the positions of bodies we may better take the stationary positions of bodies one by one, as the S.P.'s play the leading part. First, note whether the stationary position is above or below its horizon; and in Type 1 take the birth S.A. and M.D. of the S.P. and the S.A. of D.B. similar to S.P., and moderate the birth M.D. of S.P. to the similar S.A. of D.B.: and in Type 2 take the birth S.A. and M.D. of S.P. also as at birth, but the S.A. of D.B. opposite to S.A. of S.P., and moderate the M.D. of S.P. to the opposite S.A. of D.B. Now, see if D.B. has to cross or not the M.H.P. to parallel the S.P., accordingly settle whether the parallel is of Case (i) or (ii), and proceed to find the A.D. applying Rule XXII. In most cases it can be readily judged by mere inspection whether a D.B. has to cross or not the M.H.P. without actually carrying out all the tedious moderations. So a schedule of M.D.'s of S.P.'s only for cases when D.B. has to cross or not the M.H.P. need be moderated to the particular S.A. of D.B. All the same, in Schedule X the M.D.'s of every S.P. stand moderated to both S.D.A. and S.N.A. of every D.B.

Exercise 38-Prepare the schedule of the birth M.D.'s of S.P.'s moderated to (a) S.D.A. and (b) S.N.A. of every D.B. in the standard nativity.

LESSON IV

- 88. Rapt Parallel—In all directions described till now, only one body was moved while the other remained stationary. But in a direction to rapt parallel both the bodies are simultaneously moved while the equatorial arc between them remains the same. Angles do not form rapt parallel. The equatorial arc with a body at its either end may be compared to a garland with a pendant at each end. Two bodies are said to be in rapt parallel when they stand at distances from a meridional half, proportionate to their S.A.'s appropriate to the M.H. A rapt parallel is a primary direction, since it is formed within 24 sidereal hours after birth, and is caused by the apparent diurnal rotation of the heavens. And it is a mundane direction, because the arc of direction is measured upon the equatorial arc. In direct rapt parallel the arc is moved clockwise to the meridional half of parallel: and in converse rapt parallel the arc is moved anti-clockwise to the meridional half of parallel.
- 89. Direct Body and the Passive Body—The two bodies concerned in a rapt parallel are known as the Directed Body (D.B.) and the Passive Body (P.B.), there being no S.P. In a direct rapt parallel the directed body is the one at the anti-clockwise end of the equatorial arc; and in a converse rapt parallel it is the one at the clockwise end of the equatorial arc. In either case, the body at the other end of the equatorial arc is the passive Body. The D.B. always pushes before it the P.B. but never drags the P.B.
- 40. Are of Parallel—In a rapt parallel the equatorial arc between the D.B. and the P.B. is the arc of parallel (A.P.), for it is the one that is moved clockwise [anti-clockwise] to the meridional half of parallel (M.H.P.). In direct rapt parallel, the arc of parallel is measured clockwise from D.B. to P.B.: and in converse rapt parallel, anti-clockwise from D.B. to P.B. Since the A.D. obtained, with one arc parallelled upon an M.H.P. is identically the same as the A.D. obtained with the other arc parallelled upon the other M.H.P.; therefore, it will do, if one and only one of the two arcs between a D.B. and a P.B., which are the explements of one another, is taken—the clockwise arc from D.B. to P.B. in converse ones. The angular measurement in equatorial degrees of the clockwise A.P. is obtained by deducting the right ascensional degrees and minutes of P.B. from the right ascensional degrees and minutes of D.B.; and the measurement of the anti-clockwise A.P. in converse ones by deducting the R.A. of D.B. from

the R.A. of P.B. If the R.A. to be deducted from is numerically less than that of the other, add 360° to it and then deduct.

Dictum III—When the angle to be deducted from is numerically less than the other, add 360° to it.

But whether the difference is more than 180° or not, leave it as it is with no rectification.

So Dictum II does not apply here. For, we want only the clockwise or anti-clockwise arc but not the shorter distance, the aspect being a parallel and not an angular one. For example, in the direct rapt parallel of Saturn to Sun, the R.A. of Saturn is 203° 16′ and the R.A. of Sun is 70° 58′, and so the A.P. is 203° 16′—70° 58′ i.e., 132° 18′; and in the converse rapt parallel of Neptune to Mars, the R.A. of Neptune is 9° 55′ and the R.A. of Mars is 128° 20′, so the A.P. is 128° 20′—9° 55′, i.e., 118° 25′. Therefore, we have

Rule XXIII.—In direct rapt parallels, A.P. = R.A. of D.B.—R.A, of P.B. Add 360° to the R.A. to be deducted from, if it is numerically less.

In converse ones A.P. = R.A. of P.B. - R.A. of D.B.

Meridional Half of Parallel—In direct rapt parallells, D.B. is moved to its first clockwise M.H. (Case i), and if no rapt parallel is formed on the first clockwise M.H., the D.B. is moved continuously or in the same clockwise manner to its second clockwise M.H. (Case ii). In converse rapt parallels, the D.B. is moved to its first anti-clockwise M.H. (Case i), and if no rapt parallel is formed on the first anti-clockwise M.H., the D.B. is moved continuously or in the same anti-clockwise manner to its second anti-clockwise M.H. (Case ii). For example, in the direct rapt parallel of Saturn to Sun, the first clockwise M.H. is L.M.H., and the second clockwise M.H. is the U.M.H.: and in the converse rapt parallel of Neptune to Mars, the first anti-clockwise M.H. is the L.M.H. and the second anti-clockwise M.H. is the U.M.H. Therefore, we have

Rule XXIV.—In Case (i) of direct and converse rapt parallels, the M.H.P. is the first clockwise or anti-clockwise M.H. of D.B.: in Case (ii) of direct and converse rapt parallels the M.H.P. is the second clockwise or anti-clockwise M.H. of D.B.

42. The First M.D. of D.B.—In direct rapt parallels the mundane distance at birth of the D.B. from its first or second clockwise M.H., as the case may be, is the first M.D. of D.B. In converse rapt parallels the mundane distance at birth of the D.B. from its first or second anti-clockwise M.H., as the case may be, is the first M.D. of D.B. For example, in the direct rapt parallel of Saturn to Sun, in Case (i), the first M.D. of Saturn is its L.M.D. 112° 24', and in Case (ii) the first M.D. of Saturn is its U.M.D. 67° 36', In the converse rapt parallel of

Neptune to Mars of Case (i) the first M.D. of Neptune is its L.M.D. 80° 57', and of Case (ii) the first M.D. of Neptune is its U.M.D. 99° 3'. Therefore, we have

Rule XXY—The first M.D. of D.B. is always the birth M.D. of D.B. taken appropriate to the M.H.P.

48. The Second M.D. of D.B.—In direct rapt parallels, the mundane distance at parallel of the D.B. from its M.H.P. is the second M.D. of D.B. In converse rapt parallels the mundane distance at parallel of the D.B. from its M.H.P. is the second M.D. of D.B. It is obtained in both direct and converse rapt parallels by dividing the A.P. proportionately to the S.A.'s of D.B. and of P.B. at parallel. The division is carried out as follows:—

S.A. of D.B. at | + S.A. of P.B. at | : S.A. of D.B. at | : : A.P. : 2nd M.B. of D.B.

For example, in the direct rapt parallel of Saturn to Sun the first clockwise M.H. is L.M.H., the sum of the S.N.A.'s of Saturn and Sun is 98° 38' + 59° 9', i.e., 157° 47', the S.N.A. of Saturn is 98° 38', and the A.P. is 132° 18' (see Schedule XI).

- : 157° 47′: 98° 38′:: 132° 18′: the second M.D. of D.B.
- \therefore (a.c.) 9'94279 + 0'26125 + 0'13371 = 0'33775, T.P.L. of 82° 42'.
- The second M.D. of D.B. is 82° 42′.

Again, in the direct rapt parallel of Neptune to Mars, the first clockwise M.H. is U.M.H., the sum of the S.D.A.'s of Neptune and Mars is 93° 19' + 117° 31' i.e., 210° 50', the S.D.A. of Neptune is 93° 19' and the A.P. is 241° 35' (see Schedule XI).

- : 210° 50': 93° 19': 241° 35' the second M.D. of D.B. from U.M.H.
- : 21° 5': 93° 19': 24° 9'5' the second M.D. of D.B.

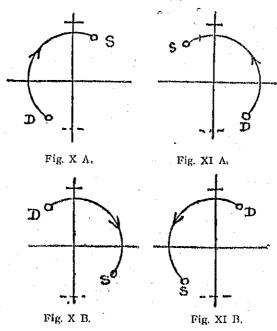

(a.c.) 9'06867 + 0'28531 + 0'87221 = 0'22619, the T.P.L. of 106° 56', the second M.D.

One tenth of the first and the third term have been taken to bring their values below 180° for which only T.P.L.'s are given in the Tables (see Articles 51 and 200 of Mathematical Astrology). Therefore, we have

Rule XXVI.—In all cases, the second M.D. of D.B. is obtained as:—S.A. of D.B. at || + S.A. of P.B. at || : : A.P. : 2nd M.D. of D.B.

44 Arc of Direction—The arc of direction is the equatorial arc through which D.B. is moved clockwise in direct, or anti-clockwise in converse rapt parallels from its mundane position at birth to its mundane position at parallel. It is the arc from first M.D. to second M.D. from M.H.P. In Case (i) of both direct and converse rapt parallels, the first M.D. of D.B. is greater than the second M.D. of D.B., and the A.D. is obtained by deducting the second M.D. of D.B. from the first M.D. of D.B., (see Fig. X A and XI A). And in Case (ii) of both direct and converse rapt parallels, the first M.D. of D.B. is less than the second M.D. of D.B., and the A.D. is obtained by deducting the sum of the first

M.D. of D.B. and the second M.D. of D.B. from 360°, (see Fig. X B and XI B.) For example, in the direct rapt parallel of Saturn to Sun the first M.D. of Saturn is 112° 24′, and the second M.D. of Saturn is 82° 42′.

Direct, - Rapt Parallels,-Converse,

Case (i) A.D. = $112^{\circ} 24' - 82^{\circ} 42' = 29^{\circ} 42'$.

And in the direct rapt parallel of Neptune to Mars the first M.D. of Neptune is 99° 3′, and the second M.D. of Neptune is 106° 56′. As the first M.D. of D.B. is less than the second M.D of D.B., the parallel is upon the second clockwise M.H. or L.M.H. So a fresh moderation has to be made appropriate to the L.M.H. as follows, the sum of the S.N.A's. of Neptune and Mars is 86° 41′ + 62° 29′, i.e., 149° 10′, the S.N.A. of Neptune is 86° 41′, and the A.P. the same 241° 35′ (see Schedule XI):—

149° 10′: 86° 41′: 241° 35′: the second M.D. of D.B. from L.M.H. 14° 55′: 86° 41′: 24° 9′5′: the second M.D. of D.B. (a.c.) 8′91840+0′31734+0′87221=0′10795, T.P.L. of 140° 23′.

The second M.D. of D.B. is 140° 23' and the first M.D. or L.M.D. of Neptune is 80° 57'.

Case (ii) A.D. = $360^{\circ} - (80^{\circ} 57' + 140^{\circ} 23') = 360^{\circ} - 221^{\circ} 20' = 138^{\circ} 40'$

The A.D. is beyond the span settled upon, and so the rapt parallel will be late in life. Therefore, we have

Rule XXVII.—In Case (i) of both direct and converse rapt parallels,

A.D. = the first M.D. of D.B.—the second M.D. of D.B. from M.H.P.

In Case (ii) of both direct and converse rapt parallel,

A.D. = 360° - (first M.D. of D.B. + second M.D. of D.B. from M.H.P.) In Case (i) it will be evident that the D.B. does not cross its first clockwise M.H. in direct parallels, and its first anti-clockwise M.H. in converse parallels: but that in Case (ii) the D.B. crosses its first clockwise M.H. in direct parallels, and its first anti-clockwise M.H. in converse rapt parallels. It may be stated that rapt parallels of Case (ii) will always be late, and so may very well be ignored leaving only Case (i) as the probable one to be calculated.

Determination of all Rapt parallels-For this purpose, a certain age limit has, as usual, first to be fixed upon, as there is no use in calculating arcs of directions that may point to a time too long after birth. Having settled upon an ago limit, (i) enter in a vertical column all the possible permutations of two bodies taken at a time in some definite order to avoid any possible permutation escaping notice, say by taking the D.B. next clockwise to L.M.H. in direct ones and the D.B. next anti-clockwise to U.M.H. in converse ones, pairing each D.B. in succession with the P.B.'s more and more clockwise to it in direct ones, and more and more anti-clockwise to it in converse ones. As there are 9 bodies to act as D.B.'s of the remaining 8 bodies, for a D.B. cannot from a rapt parallel with itself, so we will obtain 9 × 8 or 72 possible permutations. (ii) Next, enter similarly, the M.D. of each D.B. at birth from its first clockwise M.H. in direct ones, and from its first anti-clockwise M.H. in converse ones, and note as well whether the first M.D. of D.B. is from upper or lower M.H. (iii) Next, determine the A.P.'s of each permutation of bodies, and enter similarly half of it as the approximate second M.D. of D.B. For, the S.A. of either D.B. or P.B. is only about a few degrees more or less than 90°, and so the S.A. of D.B. is always very nearly half the sum of the two S.A.'s. Therefore, A.P. which has to be divided into two parts proportionately to the S.A.'s, may be halved and taken as the very approximate second M.D. of D.B. (iv) Now by mere inspection, decide whether the first M.D. of D.B. is greater than the second M.D. of D.B., and whether the difference between the two M.D.'s falls within the age limit. If so, it is a probable rapt parallel of Case (i); if not, the rapt parallel will be too late in formation. And when the first M.D. of D.B. is less than its second M.D., then add the two M.D.'s and see if the explement of their sum falls within the age limit. If so, it is a probable rapt parallel of Case (ii); if not, it will be too late. And lastly, (v) determine the A.D. of Case (i) or of Case (ii) if necessary, finding the first M.D. of D.B. from M.H.P., and by a fresh moderation the second M.D. of D.B. from M.H.P. It may be observed that the possible number of permutations of Case (ii) will be about half the number of those of Case (i), i.e., 36.

To facilitate the calculation of all rapt parallels, a schedule containing (i) the R.A.'s of bodies with the difference in R.A. between two consecutive bodies, (ii) both the S.A.'s of every body, noting the birth ones, and (iii) both the M.D.'s of every body, noting the birth ones, may be preliminary prepared, (see schedule XI).

Schedule XI-The R.A.'s, S.A.'s and M.D.'s of Bodies.

N. B.—The birth S.A.'s and M.D.'s are set in thick types in the schedule.

Exercise 39-Prepare a schedule of the R.A.'s, S.A's and M.D.'s of bodies in the standard nativity.

Problem 20-Find the A.D. of the direct rapt parallel of Uranus to Mars.

The Cl. D. or A.P. from Uranus to Mars = $360^{\circ} + 88^{\circ} 30' + 128^{\circ} 20' = 320^{\circ} 10'$. The first clockwise M.H.P. is U.M.H.

First M.D. of D.B. is the U.M.D. of Uranus at birth = 177° 38'.

S.D.A. of Uranus + S.D.A. of Mars = 123° 12' + 117° 31' = 240° 43'.

240° 43': 123° 12':: 320° 10': the second M.D. of D.B.

120° 21"5: 123° 12':: 160° 5':

(a.c.) 9'82520+0'16466+0'05093=0'04079, T.P.L. of 163° 52'.

Case (i) A.D. = 177° 38' - 163° 52' = 13° 46'.

∴ A.D. of w R.P. s (Dir.) is 13° 46'.

Problem 21-Find the A.D. of the direct rapt parallel of Venus to Mars.

The Cl. D. or A.P. from Venus to Mars. = $360^{\circ} + 37^{\circ} 43' - 128^{\circ} 20' = 269^{\circ} 23'$.

The First Cl. M.H. is U.M.H.

First M.D. of D.B. is the U.M.D. of Venus = 126° 51'.

S,D.A. of Venus + S.D.A. of Mars = $107^{\circ} 10' + 117^{\circ} 31' = 224^{\circ} 41'$.

224° 41′; 107° 10′; : 269° 23′; the second M.D. of D.B.

112° 20"5: 107° 10':: 134° 41"5:

(a.c.) $9.79527 \div 0.22521 + 0.12593 = 0.14641$, T.P.L. of $128^{\circ} 29^{\circ}$.

First M.D. of D.B. is less, so parallel afresh on the second Cl.M.H. or L.M.H. A.P. is same, i.e., 269° 23'.

The first M.D. of ? is its L.M.D. 53° 9'.

S.N.A. of Venus + S.N.A. of Mars = 72° 50' + 62° 29' = 135° 19'.

135° 19′ : 72° 50′ : : 269° 23′ : the second M.D. of D.B. from M.H.P.

67° 39′5 : 72° 50′ : : 134° 41″5 :

(a.c.) 9'57505 + 0'39294 + 0'12593 = 0'09392, T.P.L. of 145° 0'.

Case (ii) A.D. = $360^{\circ} - (53^{\circ}19' + 145^{\circ}0') = 161^{\circ}51'$.

... A.D. of ? R.P. & (Dir.) is 161° 51', which will be late.

Exercise 40—Find the A.D.'s of all the direct rapt parallels of Mars to all other bodies in the standard nativity.

Exercise 41—Find the A.D.'s of all the converse rapt parallels of Saturn to all other bodies in the standard nativity.

LESSON V

PRIMARY ZODIACAL DIRECTIONS

- Primary Zodiacal Directions-Primary zodiacal directions are called primary, for they are formed within 24 sidereal hours after birth, and so earlier than the secondary directions to be taken up next. Primary zodiacal directions are on all fours, so far as they can be, with the primary mundane directions, except in regard to certain points. The most outstanding difference is that primary zodiacal directions rest on the phenomenon of the anti-clockwise annual motion of bodies, while the primary mundane directions rest on that of the clockwise apparent diurnal rotation of the heavens. Though primary zodiacal directions rest on anti-clockwise annual motion of bodies, yet (i) their zodiacal motion is taken to be at the rate of the apparent diurnal rotation of the heavens, and (2) arcs of directions are measured upon the ecliptic and then referred to the equator, and are made to measure time similarly to primary mundane directions. So the aspects are first measured upon the ecliptic and then referred to the equator. Theoretically speaking, primary zodiacal directions may be to the position of one of the two angles or of a body, to zodiacal parallel, and to zodiacal rapt parallel.
- 47. Primary Zodiacal Directions of the Angles and to the Bodies—In primary mundane directions to angles, the latter are deemed to be the S.P.'s and the bodies to be the D.B.'s. But in primary zodiacal directions, the angles are deemed to be the D.B.'s and the bodies to be the S.P.'s. So in primary zodiacal directions of angles, the angles are written first, e.g., M.C. \triangle O, while in primary mundane directions the angles are written second, e.g., \bigcirc \triangle M.C. And in primary zodiacal directions of bodies to aspects of positions of bodies, the bodies, as usual, are the D.B.'s and the positions are the S.P.'s. Subject to this difference, and the consequent alterations, primary zodiacal directions of angles, and those to bodies may be discussed together as it was done in the case of mundane directions.
- 48. Direct and Converse Directions—The phenomenon underlying primary zodiacal directions being the anti-clockwise annual motion of bodies, all directions in which the D.B.'s, whether an angle or a body, are moved anti-clockwise are the direct ones, and those in which the D.B. are moved clockwise are the converse ones.
- 49. Shorter Distance—In direct directions we require the anti-clockwise zodiacal distance from D.B. (angle or body) to S.P., and in converse ones the clockwise zodiacal distance from D.B. to S.P. The anti-clockwise zodiacal dis-

tance in direct directions is obtained by deducting the D.B.'s celestial longitude from the S.P.'s celestial longitude. The clockwise zodiacal distance in converse ones is obtained by deducting the S.P.'s longitude from D.B.'s longitude. When the longitude to be deducted from is numerically less than the other, add 360° to it and then deduct. For example, the anti-clockwise distance in the direct direction of Jupiter to Neptune is 360° 0' + 10° 10' - 265° 40'. i.e., 104° 30': and the clockwise distance in the converse one of M.C. to Sun is 270° 47' - 72° 26', i.e., 198° 21'. Therefore, we have.

Rule XXVIII—Anti-clockwise distance from D.B. to S.P.=S.P.—D.B.,
Clockwise distance from D.B. to S.P.=D.B.—S.P.

And when the longitude to be substracted from is less than the other, add 360° to it and then deduct.

But we require always the shorter distance between D.B. and S.P., for all aspect angles are less than 180°. The shorter distance is the anti-clockwise or clockwise distance itself when it does not exceed 180°; but when it exceeds 180°, the shorter distance is always obtained by deducting the anti-clockwise or clockwise distance from 360°. For example, the anti-clockwise distance from Jupiter to Neptune being 104° 30′, is itself the S.D., but the clockwise distance from M.C. to Sun being 198° 21′, the shorter distance from M.C. to Sun is 360° 0′ – 198° 21′, i.e., 161° 39′. Therefore, we have,

Rule XXIX-S.D. = Acl. D. or Cl. D., when the latter is less than 180°.

S.D. = 360°-Acl. D. or Cl. D., when the latter is greater than 180°.

When the anti-clockwise or clockwise distance has not been rectified to obtain the shorter distance, the direction, whether direct or converse, is one of Case (i): and when the anti-clockwise or clockwise distance has been rectified to obtain the shorter distance, the direction, whether direct or converse, is one of Case (ii).

of direct and converse ones, that is, when the anti-clockwise or clockwise distance has not been rectified to obtain the shorter distance, the first aspect angle is just less than the shorter distance, and the subsequent ones decrease till conjunction and then increase. In Case (ii) of direct and converse ones, that is, when the anti-clockwise or clockwise distance has been rectified to obtain the shorter distance, the first aspect angle is just greater than the shorter distance, and the subsequent ones increase till opposition and then decrease. For example, in the direct directions of Jupiter to Neptune the unrectified shorter distance is 104° 30′, so the first aspect angle is the one just less than the S.D., i.e., square or 90°, and the subsequent ones decrease from square up to conjunction, and then they increase, e.g., sextile to conjunction, and then to sextile, square and so on. And in

the direct direction of the M.C. to Moon the rectified shorter distance is 89° 44′, so the first aspect angle is the one just greater than the S.D., i.e., square or 90°, and the subsequent ones increase from trine up to opposition, and then they decrease, e.g., trine to opposition, and then trine, square and so on. Therefore we have,

Rule XXX—In Case (i) the first aspect angle is just less than S.D., and the subsequent ones decrease till conjunction, and then increase.

In Case (ii), the first aspect angle is just greater than S.D., and the subsequent ones increase till opposition, and then decrease.

51. The Position of the D.B. at the end of a Direction—Aspect angles are the zodiacal aspect extents. They are always measured from the S.P.'s towards the D.B.'s as in primary mundane directions; but clockwise in direct ones and anti-clockwise in converse ones. The point where the measurement ends is termed the limit or the position of the D.B. at the end of the direction. In direct directions the limit will be anti-clockwise of the D.B., and in converse ones it will be clockwise of the D.B.

Whether S.D. has been obtained by rectification or not, (1) in direct directions the limit of an aspect from opposition to conjunction, i.e., of the decreasing series, is the S.P.'s longitude minus the aspect angle, (2) in direct directions the limit of an aspect from conjunction to opposition, i.e., of the increasing series, is the S.P.'s longitude plus the aspect angle; (3) in converse ones the limit of an aspect from opposition to conjunction, i.e., of the decreasing series, is the S.P.'s, longitude plus the aspect angle, and (4) in converse ones the limit of an aspect from conjunction to opposition, i.e., of the increasing series, is the S.P.'s longitude minus the aspect angle.

For example, (1) in the direct direction of Jupiter to the decreasing square of Neptune, the limit is the zodiacal point $360^{\circ} 0' + 10^{\circ} 10' - 90^{\circ} 0'$, i.e., $280^{\circ} 10'$; (2) in the direct direction of M.C. to the increasing square of Moon, the limit is the zodiacal point $181^{\circ} 3' + 90^{\circ} 0'$, i.e., $271^{\circ} 3'$; (3) in the converse direction of Uranus to the decreasing sextile of Neptune, the limit is the zodiacal point $10^{\circ} 10' + 60^{\circ}$, i.e., $70^{\circ} 10$; and (4) in the converse direction of the Ascendant to the increasing square of Uranus, the limit is the zodiacal point $360^{\circ} 0' + 88^{\circ} 37' - 90^{\circ} 0'$, i.e., $358^{\circ} 37'$. Therefore, we have.

Rule XXXI—In Cases i and ii of a direction,

- (1) in direct ones to a decreasing and in converse ones to an increasing aspect,

 Limit's long. = S.P.'s long.—Aspect Angle:
- (2) in direct ones to an increasing and in converse ones to a decreasing aspect,

 Limit's long. = \$.P.'s long. + Aspect Angle.

The limits have always to be taken with no latitude, that is, as if they were ecliptic points, in calculating their R.A.'s, O.A.'s, S.A.'s and M.D.'s required for determining the A.D's in the different kinds of primary zodiacal directions, a subject to be discussed presently (see Schedule XV).

52. The Arc of Direction in directions of the Angles—So far, the description applies in common to directions of M.C., Ascendant, and Bodies to the positions of bodies. But from this point the methods vary.

Whether the direction is of Case (i) or (ii), (1) in direct ones of M.C. to the positions of bodies, the A.D. is the limit's R.A. minus the D.B.'s (M.C.'s) R.A.: (2) in converse ones of M.C., the A.D. is the D.B.'s (M.C.'s) R.A. minus the limit's R.A.: (3) in direct ones of the Ascendant to the positions of bodies, the A.D. is the limit's O.A.H. (Oblique Ascension when at the horizon, see Mathematical Astrology Art. 100) minus the Ascendant's O.A.H.: and (4) in converse ones of the Ascendant, the A.D. is the Ascendant's O.A.H. minus the limit's O.A.H. For example, in the direct directions of the Meridian to Moon the A.D. is limit's R.A. or 271° 9'—M.C.'s R.A. or 270° 52', i.e., 0° 17'; and in the converse direction of the Ascendant to Jupiter (where the clockwise distance is 360° + 2° 3'—265° 40', i.e., 96° 23', the first aspect is Ascendant square Jupiter, and the limit 265° 40' + 90', i.e., 355° 40), the A.D. is the Ascendant's O.A.H. or 0° 52' minus the limit's O.A.H. or 358° 10', i.e., 2° 42'. Therefore, we have

Rule XXXII.—In both Cases (i) and (ii),

- (1) In the direct direction of M.C., A.D. = Limit's R.A. M.C.'s, R.A. In the converse directions of M.C., A.D. = M.C.'s R.A. Limit's R.A.
- (2) In the direct directions of the Ascendant, A.D. = Limit's O.A.H. Asc.'s O.A.H. In the converse ones of the Ascendant, A.D. = Asc.'s O.A.H. Limit's O.A.H.
- 53. The Arc of Direction in directions of Bodies—First, take the birth M.D. of the directed body taken with latitude, from the meridional half appropriate to the limit. Next, moderate the M.D. of the limit to the S.A. of the directed body taken with latitude and appropriate to the limit. Therefore, we have

Rule XXXIII—Take the limit with no latitude, and moderate its M.D. to the S.A. of the D.B. taken with latitude and appropriate to the S.A. of the limit:—

Limit's S.A.: limit's M.D.:: S.A. of D.B.: mod. M.D. of limit.

In the directions of bodies also two cases arise, as the D.B. crosses or not its first M.H.:—

(i) when the directed body has not to cross its first anti-clockwise meridional half in direct directions [first clockwise M.H. in converse ones] to reach the limit (see Fig. XII A. and XIII A).

(ii) when the directed body has to cross its first anti-clockwise meridional half in direct directions [first clockwise M.H. in converse ones] to reach the limit (see Fig. XII B and XIII B).

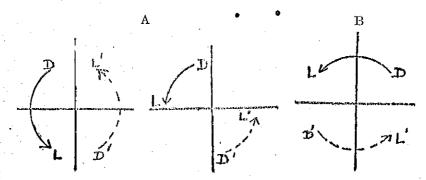

Fig. XII-Direct Primary Zodiacal Directions.

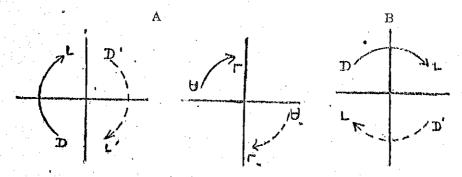

Fig. XIII-Converse Primary Zodiacal Directions.

- (1) In the direct directions of Mars to Moon the Acl. D. is 55° 28' which is the unrectified S.D., the first A.E. is the decreasing conjunction, and the first limit is 181° 3'; so Mars, the D.B., has not to cross its first anti-clockwise M.H. to reach the limit (Case i). The limit's S.N.A. is 90° 31', and its L.M.D. is 90° 6', and the S.N.A. of Mars taken with latitude is 62° 29', and its L.M.D. 37° 28'.
 - 90° 31': 90° 6':: 62° 29': moderated M.D. of the limit.
 0'00201 + 0'45951 = 0'46152, T.P.L. of 62° 12'.
 Mars, the D.B., when taken with latitude, its L.M.D. is 37° 28'.
 - \therefore A.D. = 62° 12′ 37° 28′ = 24° 44′, Case (i).
 - . The A.D. of the direct & & D is 24° 44'.
- (2) In the converse direction of Uranus to Neptune, the Cl. D. is 78° 27 which is the unrectified S.D., the first A.E. is the decreasing sextile, and the first limit is 70° 10′; so Uranus, the D.B., has not to cross its first clockwise

M.H. to reach the limit (Case i). The limit's S.N.A. is 59° 43', and its L.M.D. 22° 20', and the S.N.A. of Uranus taken with latitude is 56° 48', and its L.M.D. 2° 22'.

- .. 59° 43′: 22° 20′:: 56° 48′: moderated M.D. of the limit. 0'42714-1-0'50092 = 0'92806, T.P.L. of 21° 15′
- \therefore A.D. = 21° 15′ 2° 22′ = 18° 53′
- ∴ The A.D. of the converse w * Ψ is 18° 53'.
- (3) In the direct direction of Venus to Uranus, the Acl. D. is 48° 58′ which is the unrectified S.D., the first A.E. is the decreasing conjunction, and the first limit is 88° 37′; so Venus, the D.B., has not to cross its first anti-clockwise M.H. to reach the limit (Case i). The limit's S.N.A. is 57° 9′, and its L.M.D. 2° 22′, and the S.N.A. of Venus taken with latitude is 72° 50′, and its L.M.D. 53° 9′.
 - ∴ 57° 9′: 2° 22′:: 72° 50′: moderated M.D. of the limit, 1'38288 + 0'39294 = 1'77582, T.P.L. of 3° 1′.
 - \therefore A.D. = 53° 9′ 3° 1′ = 50° 8°.
 - ∴ The A.D. of the direct ? & W is 50° 8'.
- (4) In the converse direction of Moon to Mars the Cl. D. is 55° 28' which is the unrectified S.D., the first A.E. is the decreasing conjunction, and the first limit is 125° 35'; so Moon, the D.B., has not to cross its first clockwise M.H. to reach the limit (Case i). The limit's S.N.A. is 64° 41', and its L.M.D. 37° 5'; and the S.N.A. of Moon taken with latitude is 93° 20', and its L.M.D. 89° 7'.
 - .. 64° 41′; 37° 5′:: 93° 20′: moderated M.D. of the limit.
 - \therefore 0'24161 + 0'28524 = 0'52685, T.P.L. of 52° 31'.
 - $A.D. = 89^{\circ} 7' 52^{\circ} 31' = 36^{\circ} 36^{\circ}.$
 - : The A.D. of the converse D of is 36° 36'.
- (5) In the direct direction of Jupiter to Neptune, the Acl. D. is 104° 30′ which is the unrectified S.D., the first A.E. is the decreasing square, and the first limit is 280° 10′; so Jupiter, the D.B., has to cross its first anti-clockwise M.H. to reach the limit (Case ii). The limit's S.D.A. is 57° 50′, and its U.M.D. 10° 12′; and the S.D.A. of Jupiter taken with latitude is 58° 4′, and its U.M.D. 5° 35′.

57° 50': 10° 12':: 58° 4'; moderated M.D. of the limit.

- \therefore 0'75358 + 0'49135 = 1'24493, T.P.L. of 10° 14'.
- \therefore A.D. = 10° 14′ + 5° 35′ \sim 15° 49′.
 - . The A.D. of the direct n α Ψ is 15° 49'.
- (6) In the converse direction of Mars to Uranus the Cl. D. is 36° 58′ which is the unrectified S.D., the first A.E. is the decreasing conjunction, and the first limit is 88° 37′; so Mars, the D.B., has to cross its first clockwise M.H. to

reach the limit (Case ii). The limits's S.N.A. is 57° 9', and its L.M.D. 2° 22"; and the S.N.A. of Mars taken with latitude is 62° 29', and its L.M.D. 37° 28'.

- ∴ 57° 9′: 2° 22′; : 62° 29′: moderated M.D. of the limit. 1'38288 + 0'45951 = 1'84239, T.P.L. of 1° 35′.
- \therefore A.D. = 37° 28′ + 1° 35′ = 39° 3′.
- .. The A.D. of the converse & & 14 is 39° 3'. Therefore, we have

Rule XXXIV.—In Case (i) where D.B. has not to cross its first M.H.,

A.D. = M.D. of D.B. ~ mod. M.D. of limit.

In Case (ii) where D.B. has to cross its first M.H.,

A.D. = M.D. of D.B. + mod. M.D. of limit.

To facilitate calculations of primary zodiacal directions to bodies (i) a schedule of the S.D.'s between the various permutations of bodies taken two a time, noting whether each was obtained by rectification or not (see Schedule XIII), (ii) a schedule of the limits of all the aspects, both of the decreasing and the increasing series, of every body, (see Schedule XIV), and (iii) a schedule of the longitudes, semi-arcs, meridional distances, right ascensions, and oblique ascensions when on the horizon of the birth-place, and the ternary proportional logarithms of the ratios of the S.A's to the M.D's of all the various zodiacal limits of every body (see Schedule XV) may be preliminarily prepared. This last schedule is in fact an extensive speculum of the limits taken with no latitude. The reader will do well to calculate the A.D.'s in a series of directions of the same body to all others, when he will realise that with the change in the position of the limit the nature of all arcs change, as shown in the working of the above examples.

- 54. Directions to Zodiacal Parallel.—This is mathematically impossible. No amount of manipulation can influence the apparent diurnal rotation of the heavens to alter the annual motion in the declination of bodies.
- 56. Directions to Zodiacal Rapt Parallel.—It is a rigid impossibility to direct a body to the zodiacal rapt parallel of another body, for the annual motions of the several bodies vary vastly and independently of each other.

Problem 22—Find the A.D.'s of the direct primary zodiacal directions of M.C. to Saturn.

The rectified Acl. D. from M.C. to h is 66° 41',

- (1) The first A.E. is the increasing D, and first limit is 294° 6′. The R,A. of 294° 6′ is 296° 0′, and the R,A. of M.C. is 270° 52′.
- ... The A.D. of M.C. ... 4 (direct) = 296° 0′ 270° 52′ = 25° 8′.
- (2) Again, the next A.E. is Δ, and the limit is 324° 6'. The R,A. of 324° 6' is 326° 25', and the R.A. of M.C. is 270° 52'.
- The A,D, of M.C. \triangle b (direct) = 326° 25′ 270° 52′ = 55° 33′.

Problem 23—Find the A.D's, of the converse primary zodiacal directions of the Ascendant to Jupiter.

The unrectified Cl. D from the Ascendant to Jupiter is 96° 23'.

- The first A.E. is the decreasing □, and the first limit is 355° 40′.
 The O.A.H, of the limit is 358° 10′, and the O.A.H, of the Ascendant is 0° 52′.
- .'. The A.D. of Asc. \Box 24 (converse) = 360° 52′ 358° \Box 10′ = 2° 42′.
- (2) Again, the next A.E. is *, and the limit is 325° 40'.
 The O.A.H. of the limit is 344° 40', and the O.A.H. of the Ascendant is 0° 52'.
- .'. The A.D. of Asc. * 24 (converse) = $360^{\circ} 52' 344^{\circ} 40' = 16^{\circ} 12'$.
- (3) Again, the next A.E. is d, and the limit 265° 40'.
 The O.A.H. of the limit is 298° 0', and the O.A.H. of the Ascendant is 0° 52'.
- ... The A.D. of Asc. of 4 (converse) = $360^{\circ} 52' 298^{\circ} 0' = 62^{\circ} 52'$.

Problem 24—Find the A.D.'s of the direct primary zodiacal directions of Mars to Moon.

The unrectified Acl. D, from Mars to Moon is 55° 28'.

- (1) The first A.E. is the decreasing s₁ and the limit is 181° 3′.
 The S.N.A. of the limit is 90° 31′, and its L.M.D. is 90° 6′.
 The birth S.N.A. of D.B. taken with lat. is 62° 29′, and its L.M.D. is 37° 28′.
- ., 90° 31 : 90° 6′ ; : 62° 29′ ; moderated M.D. of S.P. 0'00201+0'45951=0'46152, T.P.L., of 62° 13′,
- ... The AD, of σ of D (direct) = 62° 13′ 37° 28′ = 24° 44′.
- (2) The D.B.'s M.D., being less, further directions will be late.

Problem 25-Find the A.D.'s of the direct primary zodiacal directions of Mercury to Neptune.

The rectified Acl, D. from Mercury to Neptune is 38° 19',

The first A.E. is the increasing *, and the first limit is 70° 10'. The S.N.A. of the limit is 59° 43', and its L.M.D. is 22° 20'. The S.N.A. of Mercury (D.B.) is 71° 36', and its L.M.D. 43° 55', 59° 43' : 22° 20' : : 71° 36' : moderated M.D. of the limit. 0'42714+0'40036=0'82750, T.P.L., of 26° 47'.

Case i. The A.D. of $\Psi \times \Psi$ (direct) = 43° 55' - 26° 47' = 17° 8'.

Here D.B.'s M.D. is greater.

(2) Again, the next A.E. is the increasing D, and the first limit is 100° 10'. The S.N.A. of the limit is 57° 50', and its L.M.D. 10° 12', The S.N.A. of Mercury (D.B.) is 71° 36', and its L.M.D. 43° 55'. 57° 56': 10° 12':: 71° 36': moderated M.D. of the limit. 0'75358+0'40036=1'15394, T.P.L. of 12° 38'. Case ii. The A.D. of $\Psi \square \Psi$ (direct)=43° 55'+12° 38'=56° 33'. The rest will be late.

Problem 26—Find the A.D.'s of the converse primary zodiacal directions of Jupiter to Saturn,

The unrectified Cl. D. from Jupiter to Saturn is 61° 34'.

- The first A.E. is the decreasing *, and the first limit is 264° 6'. The S.D.A. of the limit is 57° 24', and its U.M.D. 7° 18', The S.D.A. of Jupiter (D.B.) is 58° 4', and its U.M.D. 5° 35'. 57° 24'; 7° 18'; 58° 4'; moderated M.D. of the limit, 0'89559 + 0'49135 = 1'38694, T.P.L. of 7° 23'. Caso i. The A.D. of 24×12 (converse) = 7° 23' - 5° 35' = 1° 48',
- Here D.B.'s M.D. is less.
- (2) Again, the next A.E. is the decreasing d, and the first limit is 204° 6'. The S.D.A. of the limit is 78° 7', and its U.M.D. 68° 33'. The S.D.A. of Inpiter (D.B.) is 58° 4', and its U.M.D. 5° 35', 78° 7': 68° 33':: 58° 4': moderated M.D. of the limit. 0.05674 + 0.49135 = 0.54809, T.P.L. of 50° 57'. Case i. The A.D. of 24 d b (converse) = 50° $57' - 5^{\circ}$ $35' = 45^{\circ}$ 22'.

Here D.B.'s M.D. is less.

The rost will be late,

Problem 27—Find the A.D. in the converse primary zodiacal directions of Saturn to Mars.

The unrectified Cl. D. from Saturn to Mars is 78° 31'.

(1) The first A.E. is the decreasing *, and the first limit is 185° 35'. The S.D.A. of the limit is 87° 14', and its U.M.D. 85° 45'. The S.D.A. of Saturn (D.B.) is 81° 22', and its U.M.D. 67° 36'. 87° 14' : 85° 45' : : 81° 22' : moderated M.D. of the limit., 0.00745 + 0.34483 = 0.35228, T.P.L. of 79° 59'. Case i. The A.D. of h * 3 (converse) = 79° 59' - 67° 36' = 12° 23'.

Here D.B.'s M.D. is less,

(2) Again, the next AE is the decreasing d, and the first limit is 125° 35' The SNA of the limit is 64° H', and its LMD 37° 5' The SNA of Saturn (DB) is 98° 38', and its LMD 112° 24 64° 41'; 37° 5' ' ' 98° 38'; moderated MD of the limit 0'24161+026125=050286, TPL of 56° 33' Case 1 The AD of b d & (converse)=112° 21' - 56° 33' = 55° 51'

Here DB's MD is greater

Note that in this problem the SA, of DB changes from diurnal to nocturnal

Problem 28—Find the Λ.D.'s of the converse primary zodiacal directions of Mars to Uranus.

The unrectified Cl D from Mars to Uranus 15 36° 58′
The first AE is the decreasing 6, and the first limit 18 88° 37′
The SNA of the limit is 57° 9′, and its LMD 2° 22′
The SNA of Mars (DB) is 62° 29′, and its LMD 37° 28′
57° 9′: 2° 22′: 62° 29′: moderated MD, of the limit
138288 + 015951 = 184239, TPL, of 2° 35′
Case ii. The AD of 6.6 4 III (converse) = 37° 28′ b 2° 35′ -40° 3′

Case 11 The AD of δ of ψ (converse) = 37° 28' +2° 35' = 40° 3'

The rest will be late

Exercise 42—Prepare the schedule of the Semi-arcs of bodies taken with latitude and without latitude, giving their TPL's as shown in Schedule XII, for the standard nativity

Exercise 43—Propare the schedule of Shorter Distances, indicating whether each has been obtained by rectification or not, as shown in Schedule XIII, between every pair of bodies in the standard nativity

Exercise 44—Prepare the schedule of the Limits of the different major aspects, of both the decreasing and increasing series, of every body in the standard nativity, similar to Schedule XIV

Exercise 45—Prepare the schedule or speculum of the Longitudes, RA's, OAH's, SA's and MD's of every limit taken with no latitude, and the TPL's of the intes SA's: MD's of all the limits taken with no latitude, for the standard nativity, as shown in Schedule XV

Exercise 46—Calculate the AD's of all the primary zodiacal direct directions of MC, to the various bodies in the standard nativity.

Exercise 47—Calculate the AD's of all the primary zodiacal converse directions of the Ascendant to the various bodies in the standard nativity

Exercise 48—Calculate the AD's of all the primary zodiacal direct directions of Mercury to the various bodies in the standard nativity

Exercise 49-Calculate the A,D's of all the primary zodiacal converse directions of Saturn to the various bodies in the standard nativity

66 Are Primary Zodiacal Directions Rational?—The first feature of primary zodiacal directions that provokes thought, is that the angles are made to act as D.B.'s. The angles are fixed points through which the various zodiacal points move clockwise caused by the apparent diurnal rotation of the heavens, and anti-clockwise caused by the annual motions of bodies. How can fixed points be possibly directed? Their direct directions are anti-clockwise, and their con-

verse ones clockwise, to be in consonance with the anti-clockwise annual motions of bodies; but in reality, as it is the bodies that move anti-clockwise, the directions of angles are taken contrariwise, that is, in their direct directions they are made to move anti-clockwise, and in their converse ones clockwise, which is opposed to what is admitted to be the case in the zodiacal directions. This change seems to have been adopted to get over the difficulty of having to determine the longitudes, the R.A.'s, and the oblique ascensions of the limits measured from the angles, when the angles are treated as S.P.'s which they really are.

The next point is that the limits are taken with no latitude, that is, they are treated as mere ecliptic points. For, to determine the celestial latitude of limits we have to know its declination and right ascension, which we know not. Hence declinations of limits are taken to be identical with those of ecliptic points having the same zodiacal longitude, that is, limits are treated as if they are mere ecliptic points, and their right ascensions, oblique ascensions, semi-arcs, and meridional distances are accordingly calculated. On the other hand, the limits can very approximately be assigned their birth latitudes, as they do not appreciably change during the few sidercal hours after birth, which is the ultimate basis of all primary directions. Should this right proceedure of taking limits with their birth latitudes be adopted, then the arcs of directions would be exactly the same as those of the "opposite" primary mundane directions, thus revealing the real identity between the primary zodiacal and the primary mundane directions.

The next point to be thought over is the practice of taking directed bodies with their birth latitudes. Such a procedure is opposed to the accepted fundamental principles of directions, namely, taking all arcs similar-all diurnal or all nocturnal, and all from upper M.H., or all from lower M.H. practice in vogue of taking D.B.'s with birth latitude is palpably able, is revealed by the fact that a D.B. cannot very often be directed to the aspect of a body very close to it, and also by attempts to direct a body to the conjunction of its own position, in which latter cases the A.D. should, correctly speaking, be 0° 0'. For example, in the standard nativity in the direct direction of Venus to the sextile of Moon, the U.M.D. of D.B. at birth is 1° 5', and the moderated U.M.D. of the limit is 0° 37'. Therefore, the limit has to be directed clockwise to effect a direct direction which is opposed to the accepted principle of having to move D.B.'s anti-clockwise in direct ones and clockwise in converse ones. Instances can be multi plied. Also, if the reader attempts to calculate the A.D.'s in the direct and converse directions of a body to its own birth position, almost in every case the A.D. obtained would point to the motion of D.B. contrariwise to the accepted principles. If on the other hand, the D.B.'s at birth are also taken with no latitude then the A.D.'s obtained would be 0° 0'. In conclusion, the A.D.'s in direct and converse primary zodiacal directions would be found to be practically the same as those obtained in the opposite primary mundane directions.

In fact the primary zodiacal directions seem to be a medley between the primary mundane directions and the secondary directions to be discussed presently. They seem to have been invented and adopted just to overcome the difficulty of having to calculate primary mundane directions in which mundane positions have to be expressed in houses and cuspal distances. Unanswerable objections to the adoption of primary zodiacal directions could be raised, when an attempt is made to calculate primary zodiacal parallels. No amount of mathematical manipulation could possibly change the declination of a body due to the diurnal rotation. Again, the primary zodiacal rapt parallel would be a rigid impossibility, for bodies in their annual motion have too widely varying rates of motion to render it possible for any two of them to be moved, maintaining the zodiacal distance between them constant. For these valid reasons, we have to give up the practice of adopting primary zodiacal directions. Some authors have, in vain, attempted to cure these defects by adopting new methods.

To enable the reader to readily appreciate my contention, (1) that primary zodiacal directions are nothing but sad apologies for primary mundane directions in which the limits of bodies are taken with no latitude, (2) that in calculating primary zodiacal directions the D.B.'s also should be taken with no latitude, and (3) that primary zodiacal directions as now calculated taking limits with no latitude and D.B.'s with latitude, are anything but a medley of the above two rational principles, I append below the A.D.'s of some primary mundane directions and their analogous primary zodiacal directions. The directions of bodies are calculated firstly, taking limits with no latitude and D.B.'s with latitude: secondly, taking both limits and D.B.'s with no latitude: and thirdly, taking both limits and D.B.'s with latitude—all worked out with reference to the standard nativity. It may be pointed out that in the case of the Angles, the direct primary mundane directions are analogous to the direct primary zodiacal directions and the converse mundane ones to the converse zodiacal ones. But that in the case of Bodies, the direct primary mundane direction are analogous to the converse primary zodiacal directions and vice-versa. In this exemplification, I have illustrated only directions to conjunction and opposition, as there is no complication in

The disparity in the arcs of directions in other cases not mentioned in the above Table, is due to the dissimilarity in the various arcs taken.

Contention III-Primary Zodiacal directions are Irrational.

LESSON VI

MEASUREMENT OF TIME

- of the directed body not necessary?—In all primary directions to mundane aspects and parallels discussed in Lessons II, III, and IV, the annual motion of the directed body has not been taken into consideration. Strictly speaking, it should be taken into account, as the directed body is an actual body which has its own annual motion, contrary or similar to the clockwise rotation (see Article 58). If the directed body is a stationary one, then the correction will not be required. The annual motion of all celestial bodies, other than the Moon during six sidereal hours, equivalent to 90° of A.D., which is the maximum span, is at the most, as in the case of Mercury, about 40 minutes of arc. But in the case of the Moon it may be as much as about 4 degrees. So the arcs in the directions, especially those of the Moon, should always be corrected for its eastward annual motion.
- Determination of the Correction for the annual motion of a directed body—First, determine the daily motion in R.A. of the D.B. on the date of birth, As one solar day is equal to 1444 sidereal minutes, so the motion in 4 sidereal minutes during which period the arc of direction increases by one degree, is the daily motion divided by 361. So the correction for every degree in the A.D. is 1/361 of the D.B.'s daily motion in R.A. And the correction is always positive in the cases of Moon, Sun, and the planets in direct course, but negative in the cases of the retrograde planets. For, in the case of the sun, moon and the direct planets they always move anti-clockwise in their annual motion, and so the apparent rotation of the heavens has not only to rotate the calculated arc of direction, but also the arc moved anti-clockwise by the directed body during the sidereal time of rotation due to its annual motion: whereas in the case of the retrograde planets they move clockwise, and so the apparent rotation of the heavens has to rotate the calculated arc of direction less the arc moved clockwise by the directed body. If the twelve-hourly motion in $R.\Lambda$, of a body is taken, then we have to deduct or add 1/180th part of the twelve-hourly motion for every degree in the are of direction. If the six-hourly motion in R.A. of a body is taken, then we have to deduct or add 1/90th part of the six-hourly motion for every degree in the arc. And if the hourly motion is taken, then we have to deduct or add 1/15th part of the hourly motion for every degree in the arc.

Problem 29.—Find the correction for the annual motion of the directed body in the direct primary mundane directions of (i) Moon to the opposition of M.C., the A.D. being 89° 7′, (ii) Moon to the trine of the Horizon, the A.D. being 58° 18′, (iii) Moon to the sextile of Sun, the A.D. being 21° 0′, and (v) Moon to the rapt parallel of Uranus, the A.D. being 32° 15′,

Let us find the daily motion of Moon from Greenwhich mean mid night of June 23, 1865 to the Greenwich mean midnight of June 3-4, 1865

R.A of Moon at G.M.N on June 2-3, 1865 is 11 h. 57 m 30*89s.

- ,, 34, ,, 12 h, 42 m, 33 90s.
- The daily motion of Moon in RA at bitth was 0 h 45 m, 3 01 s. 0 h, 45 m, 3 01 s, of RA, in time is 11° 15′ 45′′15 of arc
- ∴ 1 361th part of the daily motion is 0° 1′ 52″3 of arc.

Therefore, the correction for annual motion to be applied in all directions of the Moon is 1'52" for every degree in the arcs of directions. And the correction for Moon is always positive. Therefore, the positive corrections are (i) 2° 47', (ii) 1° 49', (iii) 1° 50', (iv) 0° 39' and (v) 1° 0'.

It may be observed that this correction should always be applied at least in the cases where the daily motion in R.A. of the directed body exceeds 20 minutes of are, as the time measured to in such a case would be about one month. But the important directions being those of bodies moving slowly such as η , η , η , and ψ , this correction may be ignored in regard to them.

The Measure of Time-In primary directions, mundane and zodia cal, every degree in the A.D. measures to one year. One ordinary year consists of 365 days, and one leap year of 366 days. So one minute of arc measures to 365 ± 60 , i.e., six and one twelfth of a day in an ordinary year, and to 366 ± 60 , i.e., six and one tenth of a day in a leap year. Accordingly, every minute is made to measure six and one twelfth of a day from the buth-date during the ordinary year, and six and one tenth of a day from the birth date in a loap year. The year is not quite the calendar year, but the calendar year from buth date to birth date. The leap year is not quite the calendar leap year, but the calendar year from the birth date in which the month of February with 29 days occurs. exact dates to which every minute of aic, from one to sixty, in both an ordinary and a leap year, measures may be arranged in tabular from to enable one totreadily convert minutes in any A.D. into calendar dates. The year to which an A.D. measures is obtained by adding the number of degrees in the A.D. to the year of birth. For example, the A.D. 54° 16' in George V's nativity, would measure to a date in the year, from 1 18 a. m June 2-3, (1865 + 54) 1919, to 1-18 a. m June 2-3, 1920, which is to be taken as a leap year, since February 1920 falling within the year consists of 29 days. And 16 minutes of arc in the A.D. measures in a leap year to 16× 6'1, i.e., 98 days which counted from June 23 of 1919, falls on the 9th September 1919, so the arc of direction, 54° 16', in George V's nativity, measures to the 9th September 1919. But the arc of direction 55° 16' would measure to a date in the year from 1-18 a. m. 2 3 June, 1920, to 1 18 a. m. June 1921, which is to be taken as an ordinary year, since February 1921 falling within the year consists of 28 days. And 16 minutes of arc in the A.D. measures in an ordinary year to 16×6'083, i.e., '97 days which counted from June 2-3 of 1920 falls on the 8th September 1920, and so the arc of direction, 55° 16', in George V's nativity, measures to the 8th September 1920. So a table of the dates in both an ordinary and a leap year to which every minute in the arc of direction, from one to sixty, would measure, should be prepared beforehand to facilitate the conversion of arcs into time to which they measure (see Schedule XVI). The scheduled dates should clinch the time of the native's life-incidents accurately, subject to a negative or positive error of one day, due to decimal approximation.

Schedule XVI-Dates measured to by every minute of arc in the A.D.'s.

Finally, all the A.D.'s measuring to a year or to consecutive years of life may be arranged chronologically for comparative study.

PART II

SECONDARY DIRECTIONS

LESSON VII-GENERAL PRINCIPLES

Secondary Directions-Secondary Directions rest upon the phenomenon of the anti-clockwise annual motions of bodies in the heavens, due to the orbital revolution of the planets round the Sun, and of Moon round the Earth. In consequence, celestial bodies appear to us to be moving anti-clockwise in the heavens, each at its own rate of daily annual motion, but not at the rate of its apparent diurnal clockwise motion as in the primary directions. bodies are dislocated from their zodiacal positions at birth, and are brought to occupy new zodiacal positions. The new zodiacal positions occupied by bodies and angles after every 24 hours from birth are known as their progressed positions on the corresponding progressed dates. Bodies at their progressed positions are termed progressed bodies, while bodies at their birth positions are termed radical bodies. Thus owing to their annual motions, bodies are progrossed and are brought to new zodiacal aspects (i) to the zodiacal positions of all angles and radical bodies including themselves, and (ii) to the zodiacal positions of all angles and other progressed bodies that are slower in their annual motions than themselves (see Mathematical Astrology, Article 107). Hence, two classes of secondary directions are recognised, (i) those of the Progressed to the Radicals, and (ii) those of the Progressed to the other Progressed. Bodies have each their own daily rate of annual motion, which is about a few minutes of arc in the cases of Jupiter, Saturn, Uranus and Neptune, about one degree or over in the cases of Mars, Sun, Venus and Mercury, and about 11 to 15 degrees in the case of Moon. In the case of the angles, their daily acceleration is only about one degree. Angles have no daily annual motions of their own, as erroneously held (see Article 80). What is regarded as such is nothing but the excess after completing a full circle of 360 ecliptic degrees due to apparent diurnal rotation. secondary directions as compared with primary directions, are all slowly formed and slowly dissolved. But among themselves, those of the Moon are quicker than those of the rest, and those of O, \$, \$, and the Angles slower than that of the Moon but quicker than those of μ , ν , μ and ψ . The arc moved by each body in one day, is made to measure to one year of life. Therefore, all secondary directions that could bear fruit in 90 years of an individual's life, stand completed within 90 days after birth, though like the primary directions, they are held to bear fruit in later years measured to by the arcs of directions. As secondary directions are slowly formed and dissolved, an error of even half-an-hour in the birth-time would produce in the time measured to only a difference of about a week. Consequently, the moment of birth need not be accurately known, as in the case of the primary directions. Secondary directions are so called, because they are completed second in point of time after birth, as compared with the primary directions. In secondary directions, the aspects as well as the arcs of directions are all measured upon the ecliptic, and are not to all referred to the equator. Therefore, all secondary directions are purely zodiacal, their being no secondary mundane directions. The course of direction in secondary directions is always anti-clockwise. Very rightly, converse secondary directions are not recognised.

The Progressed Date corresponding to an Ordinal year of Life-Cardinal numbers are such as 1, 2, 3, 4, 5, 32, and 87, and ordinal numbers are such as 1st., 2nd., 3rd., 4th., 5th., 32nd., and 87th. Since one day measures to one year of life in secondary directions, so to find the directions that will operate during a particular ordinal year in an individual's life, we should cast the horoscopes for the moment of birth on the two ordinal number of days corresponding to the required ordinal year of life and its succeeding one. Ordinal numbers of time relate to current periods, but cardinal numbers of time to expired periods. secondary directions we are concerned with current periods, so we should adopt the ordinals, and adhere to it to have one system of reckoning. For example, to find the secondary directions which are held to have borne fruit in George V's 35th year, we should find the two ordinal days from birth corresponding to the 35th and the 36th year of his life. They are the 35th and the 36th day counted from the birth-day, taking it as the first. George V was born at 1-18 a.m. on June 3, 1865, so the 35th and the 36th day from birth are July 7 and 8, 1865. So we should cast horoscopes for 1-18 a.m, G.M.T., (see Art. 62) on July 7 and 8, 1865. The secondary directions found to have been completed between the two dates are held to have operated in the 35th year of his life, that is, from June 3, 1909 to June 3, 1910. Again, if we desire to find the secondary directions operating during a period of consecutive years, say, from the 27th to the 55th year in his life, i.e., from June 3, 1891 to June 3, 1919, we should cast horoscopes for 1-18 a.m. G.M.T. (see Art 62) on every day from June 29 to July 27, 1865. The date of an ordinal number of day from birth for whose moment horoscope is cast is termed the progressed date, and the horoscope cast the progressed horoscope. The ordinal year of life during which directions operate may be termed the progressed year. Therefore, we have

Rule XXXV—Date of Birth + the Ordinal number of Days - 1 = the Progressed Date.

When the result, obtained by applying the rule, exceeds the maximum number of days in the calendar month of birth, deduct from it the maximum number of calendar days and take the remainder as the date in the succeeding month; and when the result exceeds the sum of the maximum number of calendar days in the month of birth and also its succeeding one, deduct from it the sum of the maximum numbers of calendar days in the two months, and take the balance as the date in the third month. For example, George V having been born on June 3, 1865, the progressed date for the 70th day from his birth is 3+70-1 or the 72nd day from June 1, 1865. Since 72 exceeds 61, the sum of the maximum numbers of calendar days in June and July, by 11, the progressed date is August 11, 1865. Also we have

Rule XXXVI—The Calendar year of Birth + the Ordinal number of year - 1 = the Progressed year.

For example, George V having been born on June 3, 1865, the 70th year from his birth is 1865+70-1 or 1934, that is, from June 3, 1934 to June 3, 1935. A year is made to commence always from the birth date. Conversely, the ordinal number of the year of life of any calendar year beginning from the date of birth is found with the aid of

Rule XXXVII—The given Calendar year +1 - the Calendar year of Birth = the Ordinal number of year from Birth.

For example, the calendar year 1934 beginning from the birth-date, June 3 (of 1934) is 1934 + 1 - 1865 or the 70th year of life. As it has been suggested at the very outset, that all calculations will be illustrated by taking George V's horoscope, let us jot down a few momentous epochs in his life, to calculate all the secondary directions that were operating during the momentous epochs.

- 1. He was married to Queen Mary (then Princess) on July 6, 1893.
- 2. He became the Prince of Wales at the end of 1901.
- 3. He became King George V on May 6, 1910.
- 4. He ascended the throne on October 22, 1910.

The four events mentioned above transpired in his 29th, 37th, 45th and 46th years. So let us calculate all the secondary directions which operated during the four years. For this purpose, we require also the progressed moments in the succeeding years. So we shall calculate for the 29th, 30th, 37th, 38th, 45th, 46th and 47th days from birth.

Problem 30—Find the Progressed Dates and the Progressed Years in George V's nativity relating to his 29th, 37th, 45th and 46th years of life,

```

62. Progressed Moment of Birth-The moment for which progressed horoscopes are cast on every day after birth may be termed the progressed moment." It is customary to take the mean-time of birth on every succeeding day after birth and to cast horoscopes. But mean-day is only a conventional affair, whereas apparent day (see Mathematical Astrology, Art. 20) is nature's or Sun's own day. But all ephemerides give the positions and the sidereal time for mean-time only. So in casting birth horoscopes we take the Greenwich mean-time of birth for finding the positions of bodies, and the local mean-time of birth for determining the longitudes of the cusps. And in casting progressed horoscopes for every succeeding day after birth, we should first convert the local mean-time of birth into apparent time by applying to it the equation of time as applicable to mean-time on the date (see Mathematical Astrology, Article 25), Next, we should convert again the apparent time of birth into its equivalent mean-time on every progressed date by applying to it the equation of time as applicable to apparent time, on the progressed date. The equation of time at a moment is determined according to any of the methods described in "Hindu Astrological Calculations," Article 11. It may also be found from Table I which gives the longitudes of the Sun, and the precise equation of time, as applied to apparent time, for every date in 1927. The equations of time for the dates in other years are the same, varying with the longitudes of the Sun. Find it and that for an intermediate moment by Rule of Three. When equation is applied to apparent time, we get the mean-time of the progressed moment of birth. Lastly, the local mean-time of the progressed moment of birth on every progressed date should be converted into its equivalent Greenwich mean-time of birth by applying the correction for longitude expressed in time (see Mathematical Astrology, Article 37). The equation of time as applied to mean-time, required to convert it into apparent time, may be found from Table I by taking the figures with the opposite sign Thus we obtain, a series of local and Greenwich mean-times varying more or less from each other.

Problem 31—Find the Progressed Moments of birth in George V's nativity on the progressed dates of July 1, 2, 9, 10, 17, 18, and 18 of 1865, given that at birth G.M.T. was 1-18 a.m., June 2/3, 1865, that the longitude of the Sun was 72° 26', and that the longitude in time of the birth-place was 37 sec. W.

The G.M.T. of birth was I-18 a.m.

The longitude in time of the birth place is 37 sec, west.

The L.M.T. of birth was 1-17-23 a.m.

The longitude of the Sun was 72° 26'.

- .. The Equation of Time, as applicable to mean-time, on the date, was +2 m. 13 s. .
- .. The apparent time of birth was 1-17-23+0-2-13, i.e., 1 h, 19 m, 36 s, or 1-20 a.m.

We should now find the local mean-times corresponding to 1-20 a.m. local apparent time on every required progressed date, and then find again the equivalent Greenwich mean-time on every such date.

Prog.	The Sun's Long.	A.T. of Birth.	Eq. of Time as applied to A.T.	L.M.T. of* Prog. moment.	G.M.T. of Prog. moment.
July 1	99	1-20 a.m.	+3 min.	1-23 a.m.	1-23 a.m.
,, 2	100	11	+ 4 min.	1-24 a.m.	1-24 a.m.
,, 9	107	11	+ 5 min.	1-25 a.m.	1-25 a.m.
,, 10	108	91	, »_	13	13
,, 17	114	11	+6 min.	1-26 a.m.	1-26 a.m.
,, 18	115	**	**	23	1)
,, 19	116	**	25	19	

The local mean-time of birth was 1-18 a.m., and so the difference between it and the mean-times of the progressed moments of birth on the dates, vary from 6 to 9 minutes. But in extreme cases, the difference may amount to nearly 30 minutes. As one day measures to one year of life, a difference of 30 minutes in the progressed moment will produce in the time measured to, a difference of about 7 days in the secondary directions of the Progressed to the Radical, and of about 10 days in the secondary directions of the Progressed bodies to the other Progressed bodies (let alone the progressed angles for the present). It may be argued that since the difference, at its greatest, is very small, and that since time measured to in secondary directions do not clinch the date when the directions bear fruit, we might take the mean-time of birth throughout to facilitate calculations. But scientific precision requires us to go by apparent time in preference to mean-time. Therefore, I shall take the apparent time of birth as the progressed moment and proceed to cast the progressed horoscopes in George V's nativity.

68. Progressed Horoscopes—We have determined the progressed dates in Article 61, and the progressed moments of the mean-time of birth on each progressed date in Article 62. It now remains to cast the progressed horos-

^{*} The local mean-times do not differ from the Greenwich mean-times, when both of them and the equation of time are taken correct to a minute, since London, the birth-place is only 37 seconds west of Greenwich.

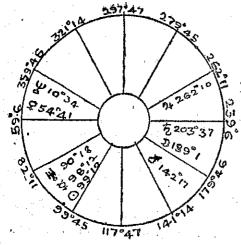

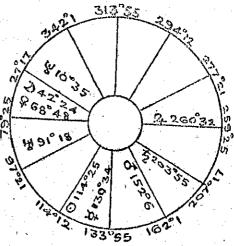

Fig. XIV—George V's Progressed Map for the 29th year, corresponding to the progressed date, 1-23 a.m., G.M.T. July 1, 1865.

Fig. XV—George V's Progressed Map of for the 45th year, corresponding to the progressed date, 1-26 a.m., G.M.T. of July 17, 1865.

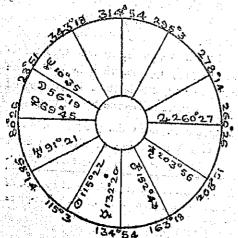

Fig. XVI—George V's Progressed Map for the 46th year; corresponding to the progressed date, 1-26 a.m., G.M.T. July 18, 1865.

copes in George V's nativity for the mean-times of birth on the several progressed dates. They are cast precisely like the horoscope of birth. But it is unnecessary to erect maps for all the horoscopes, as it will do to prepare a schedule of the longitudes and declinations of every body on each progressed date.

Problem 32—Find the longitudes and the daily motions of the two angles, the seven planets and the two luminaries at the Greenwich mean-times of birth corresponding to 1-20 a.m., apparent time, on the seven progressed dates of July 1, 2, 9, 10, 17, 18 and 19, 1865.

· See Schedule XVII, for the solution of the problem.

Problem 33—Find the declinations and the daily motions in declination of the two angles, the seven planets and the two luminaries at the Greenwich meantimes corresponding to 1-20 a.m., apparent time, on the seven progressed dates of July 1, 2, 9, 10, 17, 18 and 19, 1865.

See Schedule XVIII, for the solution of the problem.

LESSON VIII

SECONDARY DIRECTIONS

TO THE RADICALS

- 64. Secondary Directions of the Progressed to the Radicals—In this class of secondary directions the progressed body is the directed body, and the radical body is the stationary position. But the progressed angles cannot be directed, though bodies can be directed to them; for the angles are fixed mundane points with no progression of their own. An aspect is measured, as usual, either way from the radical body. As there are nine progressed bodies and eleven radicals (nine bodies and two angles), the possible number of sets of directions, each with the same progressed and radical body, is ninety-nine. The aspects directed to may be any one or more of the twelve aspects, including the parallel. The arc of direction is the angular distance from the progressed body to the limit where the aspect falls. Time is measured at the rate of one year for every one day of progression. In the notation of directions, the small letter "p" standing for 'progressed' is inserted after the symbol of the progressed body, and the small letter "r" standing for 'radical' after that of the radical body, e.g., \odot p \triangle \odot r.
- 65. Determination of the Arc of Direction—To find all the secondary directions between all the progressed bodies and the radicals, first prepare two schedules, (i) of the longitudes with the daily motions of each progressed body on every progressed date in the required period (see Schedule XVII), and (ii) of the limits of the full cycle of the eleven aspects measured from each radical (see Schedule XIX). Next, take the series of longitudes of a progressed body as given in Schedule XVII, and see which, if any, of the aspect extents as given in Schedule XIX, falls within the whole range of the longitudes of the progressed body, during the period chosen. If any aspect so falls, note (1) the progressed body, (2) the daily motion of the body, (3) the calendar year measured to by the progressed date corresponding to the longitude of the progressed body, (4) the symbol of the radical, (5) the anti-clockwise distance from each progressed body to the limit, and (6) the symbol of the aspect. The daily motion on a date, of a progressed body is the difference between its longitude on the date and that on the next succeeding date. For example, the daily motion on the sixteenth of a month is the difference between the longitude on the 16th and that on the 17th. The arc of direction is ftem (4), i.e., the anti-clockwise distance from the progressed body For example, in the lillustrated nativity, taking the progressed

Mercury on July 17, 1865, and the radical Saturn, we find that the longitude of progressed Mercury was 130° 34′ with the daily motion of +1° 46′ on the day (see Schedule XVII), and that 132° 6′, the limit of the decreasing quintile aspect of Mercury to radical Saturn (see Schedule XIX) falls between 130° 34′ and 132° 20′, the longitudes of \$\forall \text{ of July 17 and 18, 1865.} So we note the secondary direction, \$\forall p Q \cdot \hat{p} r\$, and its A.D. as 132° 6′ - 130° 34′, i.e., 1° 32′.

66. The Time measured to by an arc of direction—In the above example, the daily motion of the progressed body on the day was 1° 46′, and the calendar year measured to by the progressed date, July 17, 1865, was the year commencing from June 3, 1909. As one day measures to one year of life, so the daily motion of the progressed body has to be spread over a whole year. The arc of direction which is a fraction of the daily motion, will, as such, measure to a proportionate part of a year. Therefore, we have the proportion:—

The daily motion: A.D.:: twelve months: the number of months measured to. So the number of months measured to is obtained by multiplying the arc of direction by 12, and dividing the product by the daily motion, or what is the same, by dividing the arc of direction by one-twelfth of the daily motion. We shall adopt the latter method as we will be spared the multiplication, and will have a smaller divisor to operate with. In the above example, the number of months measured to will be 1° 32' or $92' \times 1/12$ of 1° 46', i.e., $92 \div 8'83 = 10'42$ months. To reach the time measured to, with the number of months thus obtained, count onwards from the date of birth in the corresponding progressed year. It will do, if the time measured to is reckoned correct to the corresponding ordinal calendar month, since secondary directions do not clinch the events correct to days. For example, if the horoscope under illustration for the forty-fifth day, July 17, 1865, is taken, the date will measure to the eleventh month in the year beginning from June 3, 1909. The eleventh month from June 3, 1909, is April, 1910. Therefore, the time measured to by the secondary direction ap Q ar is April, 1910, and we note as follows:--

Ψp Q hr.....April 1910.

Problem 34—Find all the secondary directions in George V's nativity of the progressed Sun to all the radicals, which operated during the four years ,June 3, 1893 to 4, 1901 to 2, 1909 to 1910, and 1910 to 1911.

The longitudes of the progressed Sun ranged during the 4 days July 1-2, 9-10, 17-18, and 18-19 from 99° 10′ to 100° 7′, 106° 47 to 107° 45, 114° 25′ to 115° 22′, and 115° 22′ to 116° 20′.

Let us take the radicals, one by one, in their order in the nativity, beginning, for the sake of convenience, from the one with numerically the smallest longitude.

- (1) To the Radical Neptune. Since no limit given in Schedule XIX falls within the four ranges of the longitudes of the Sun, so there will be no direction of the Sun to any aspect of Neptune.
- (2) To the Radical Venus. The limit, 99° 39', * to the radical Venus, falls between 99° 10' and 106° 47'.
 - : The A.D. = $99^{\circ} 39' 99^{\circ} 10' = 29'$.
 - : One-twelfth of the daily motion of ⊙ was 57÷12, i.e., 4'75.
- .. The month measured to was $29 \div 4.75$, i.e., 61 months, or the 7th month from June, 1893. So we say, $\odot p * ?r...$ December, 1893.
 - (3) To the Radical Mercury...Nil.
 - (4) To the Radical Sun...Nil.
 - (5) To the Radical Uranus...Nil.
 - (6) To the Radical Mars... Nil.
 - (7) To the Radical Moon...Nil.
 - (8) To the Radical Saturn...Nil.
 - (9) To the Radical Jupiter.;

The limit, 115° 40', was to the radical Jupiter, falls between 115° 22' and 116° 20'.

- The A.D. = $115^{\circ} 40 115^{\circ} 22 = 0^{\circ} 18'$.
- One-twelfth of the daily motion of \odot on the day was $58' \div 12 = 4'83'$.
- The month measured to was $18 \div 4'83$, i.e., 3'7 months or the 4th month from June 1910. So we say, $Op \times \mu r$... September, 1910.
 - (10) To the Radical Meridian...Nil.
 - (11) To the Radical Ascendant...Nil.

Problem 35—Find all the secondary directions in George V's nativity of the other eight progressed bodies to aspects of the eleven radicals during the four years, June 3, 1893 to 4, 1901 to 2, 1909 to 10 and 1910 to 1911.

- (i) Progressed Neptune to the Radicals...Nil.
- (ii) Progressed Venus to the Radicals.

- (vii) Progressed Saturn to the Radicals...Nil.
- (viii) Progressed Jupiter to the Radicals...Nil.
- 67. Secondary Directions to the Parallels of the Radicals—The arc of direction is determined in precisely the same manner as in secondary directions to the aspects of the radicals. To find all the parallels between all the progressed bodies and the radicals, first prepare two schedules, (i) of the declinations with the daily motions in declination of each progressed body on every progressed date during the required period (Schedule (XVIII), and (ii) the declinations of the radicals (see Schedule XX). Next, take the series of declinations of the progressed body, and note all parallels which fall between the range of the declinations of each radical taken in succession.* If any, note (1) the progressed body, (2) the daily motion in declination of the progressed body on the day, (3) the calendar year measured to by the progressed date corresponding to the declination of the progressed body, (4) the symbol of the radical, (5) the difference

^{*} A progressed body, when the range of its declinations is very wide as in the case of D, may be in parallel to the same radical more than once (see Fig. XVII).

between the declination of the radical and the declination of the progressed body just after which the declination of the radical falls, and (6) the symbol of parallel. The daily motion in declination of a progressed body on a date is the difference between its declination on the date and that on the next succeeding date. The arc of direction is the difference between the declination of the radical and that of the progressed body just after which the declination of the radical falls. The number of months measured to by the arc of direction is found just in the same way as is described in Art. 66. In Schedule XX below, the radicals are arranged in the numerical order of their declinations to facilitate the spotting of all the parallels.

Schedule XX-Declinations of the Radicals.

Asc.	D	ψ	IĮ	\$	Å	ď.	0	24	M,C,	щ
0 N 49	2 S 39	2 N 10	6 S 51	. , 13 N 17	0 , 14 N 10	%; / 20 N 17	22 N 18	22 S 56	23 S 27	23 N 39

Problem 36—Find in George V's nativity all the secondary directions of the progressed Sun to the parallel of all the radicals which operated during the four years June 3, 1893 to 4, 1901 to 2, 1909 to 10, and 1910 to 11.

The ranges of declinations of the progressed sun during the 4 progressed dates are from 22° 8' to 23° 4', 22° 24' to 22° 17', 21° 14' to 21° 6', and 21° 6' to 20° 54'.

- (i) To the Radical Neptune...Nil.
- (ii) To the Radical Venus,... Nil.
- (iii) To the Radical Mercury...Nil.
- (iv) To the Radical Sun. Its declination is 22° 18'. It falls just after 22° 24', the declination of the progressed Sun on July 9, 1865, which corresponds to June 3, 1901. The daily motion was 7'.
 ∴ The month measured to was 6÷0'6, i.e., 10, or the 11th month from June, 1909.

So we have Op | Or...April 1902.

- (v) To the Radical Uranus... Nil.

LESSON 1X

SECONDARY DIRECTIONS

TO THE PROGRESSED

- Secondary Directions of the Progressed to the other Progressed-In this class of secondary directions both the bodies are moving. So, the swifter of the two is taken as the directed body, and the slower as the body directed to, there being no stationary position. A progressed body can be directed to another slower than itself but not to itself nor to one faster than itself (see Mathematical Astrology, Art. 107). The progressed angles can neither be directed nor directed to (Art. 71). At times it may happen that the swifter of two bodies becomes, after a period, slower than the other. In such a case, the two bodies exchange their original relations-the originally swifter one now being the slower becomes the body directed to, and the originally slower one now being the swifter becomes the directed body. For example, in George V's nativity, the Sun is faster in its daily motion than Venus from June 29, 1865 to July 18, 1865, and Venus is faster than the Sun from July 19, 1865. So from June 29, 1865, the Sun is the directed body of the two, and from July 19, 1865, Venus is the directed body of the two. Hence, the Sun could be directed to Venus only till July 18, 1865, and Venus could be directed to the Sun only from July 19, 1865, but not the other way. There are nine progressed bodies, and as a progressed body could be directed only to another progressed body slower than itself, the sets of possible secondary directions, each with the same directed body and the same body directed to are 8+7+6+5+4+3+2+1 or 36 in all. In each set of directions, the aspect directed to may be one or more of the twelve aspects including the parallel. The aspects are measured, as usual, either way from the body directed to. The arc is determined differently and the time measured to is also calculated in a slightly different manner, though here too one day measures to one year. In the notation of directions, the small letter "p" is placed after both the bodies, e.g., Op A Dp.
 - 69. Determination of the Arc of Direction—To find all the secondary directions between each of the nine progressed bodies and all others slower than itself, prepare a statement of the longitudes and daily motions of each progressed body on every progressed date during the required period (see Schedule XVII). Next, take the longitude of a progressed body on the very first progressed date, and the longitude of every other progressed body moving slower than itself, on the same date. Now find the shorter distance between the progressed body and

every other slower progressed body, as they stood on the first date. This is obtained by deducting the numerically smaller longitude from the greater, and rectifying it, in case it exceeds 180°, by subtracting it from 360°. Next, take the longitudes of the same set of two bodies on the next succeeding progressed date, and again find the shorter distance between them in the same way, rectifying it, if necessary. Similarly, find the shorter distance between each pair on the consecutive progressed dates included in the required period. Now we have a series of shorter distances between the same pairs of progressed bodies corresponding to every consecutive progressed date. The shorter distances between the same two bodies on consecutive progressed dates, may be numerically increasing or decreasing. In consequence, the extents of the aspects between two sets of bodies may be increasing or decreasing. Now, take in succession every two consecutive shorter distances between the same two bodies, and see if the extent of any aspect lies between them. If so, note (1) the swifter of the two as the directed body, (2) the slower or the other progressed body, (3) the difference between the aspect extent and the first of the two consecutive shorter distances, (4) the difference between the two consecutive shorter distances, (5) the symbol of the aspect whose extent intervenes between the two consecutive shorter distances, and (6) the calendar year measured to by the first of the two consecutive progressed dates. The arc of direction is the third item, that is, the difference between the aspect extent and the first of two consecutive shorter distances between which the aspect extent lies. If no aspect extent intervenes between two consecutive shorter distances, then no direction is possible between the two bodies concerned on the day under investigation, and so none measure to the corresponding progressed year. In determining the aspect extent intervening between two consecutive shorter distances between the same two bodies, and more especially in determining the difference between two consecutive shorter distances between the same two bodies, one cannot be too careful when the two bodies approach their conjunction or opposition. As, at these two points, the shorter distances which have been decreasing or increasing till then cease to do so, and begin to become contrariwise. In the result, the real numerical difference between the consecutive shorter distances covering the conjunctional or oppositional point is much greater than what it appears to be. For example, in George V's nativity, the shorter distances between pp and up was 174° 18' on July 9, 1865, and 173° 51' on July 10, 1865. The difference between the two consecutive shorter distances between the two bodies on July 9, 1865 and July 10, 1865 appears to be 174° 18'-173° 51', i.e., 0° 27', and the next higher aspect extent of 180° or the opposition does not appear to lie between the two shorter distances. But in reality, during the 24 hours between the moments of birth on July 9, 1865 and July 10, 1865, the shorter distance between the two bodies has risen from 174° 18' to 180° 0' and then

has fallen to 173° 51' due to rectification. So the difference between the shorter distances is (180°-174° 18')+(180°-173° 51'), i.e., 11° 51' but not 0° 27' (see Problem 38). Again, the shorter distance between the same two bodies, on July 24, 1865, was 6° 2', and that on July 25, 1865, was 4° 55. So, the difference between the two consecutive shorter distances appears to be 6° 2' - 4° 55', i.e., 1° 7', but it is really 6° 2' + 4°55', i.e., 10° 57.'

Time measured to-As one day measures to one year, so the difference between two consecutive shorter distances has to be spread over a whole year Therefore, we have the proportion :---

Difference between S.D.'s: A.D.:: 12 months: month measured to. For the reason stated in Article 66, the number of months measured to by an arc of direction is found by dividing the arc by one-twelfth of the difference between the two consecutive shorter distances. To reach the time measured to with the number of months thus obtained, count onwards from the date of birth in the corresponding progressed year. As before, it will do if the time measured to is reckoned correct to a calendar month.

Problem 38.—Find in George V's nativity, all the secondary directions of progressed Moon to aspects of all the other eight progressed bodies, which operated during the four years, June 3, 1893 to 4, 1901 to 2, 1909 to 10, and 1910 to 1911.

For the solution of the problem see the statements on Pages 92 and 93.

Problem 39-Find in George V's nativity all the secondary directions of all the progressed bodies other than Moon, to the aspects of all the other seven progressed bodies, which operated during the four years from June 3, 1893 to 4. 1901 to 2, 1909 to 10, and 1910 to 1911.

Progressed Jupiter to the other Progressed... Nil.

Secondary Directions to the Parallels of the other Progressed-Here too, it is only the swifter body in its daily motion in declination that could be directed to another body. The arc is determined in precisely the same manner as in directions to aspects of the other progressed (Art. 68), except that the aspect extent of a parallel is, so to say, 0° in declination. The daily motions in declination of a progressed body varies very widely. To determine the arc of direction take the full series of declinations of a body on consecutive progressed dates during the required period, and take the declinations on the dates of one body in succession among the remaining eight progressed bodies, and see between what two dates the declinations of the two bodies coincide, having no regard to the names of the declinations. This is done by comparing the declination of each of the two bodies on the same date, to ascertain if they tend to meet or cross each other. They will tend to meet when their declinations are alike increasing or decreasing numerically: and will tend to cross when one increases while the other decreases. Whether they meet or cross, note the two consecutive progressed dates between which they meet or cross, and find the difference between their declinations on the first of the two dates. This is the arc of direction. The number of months measured to by the arc of direction, is found when the declinations of both bodies increase or decrease alike, by dividing the A.D. by one-twelfth of the difference between their daily motions in declination on the first date. And when the declination of one increases numerically, while that of the other decreases, by dividing the A.D. by one-twelfth of the sum of their daily motions in declination on the first date. Finally, take the body moving faster in declination as the directed body. Here too, one ought to be careful in finding the daily motions in declination of a body when it changes its course from north to south or south to north. For example, the declination of Moon on July 13, 1865 was 2 S 55, and on July 14, 1865, 2 N 2. So the daily motion in declination of Moon on the day was not 0° 53' but 2° 55' + 2° 2', i.e., 4° 57'. For the ranges of declinations of the nine bodies on the consecutive progressed dates, see Schedule XVIII.

Problem 40—Find in George V's nativity all the secondary directions of each of the progressed bodies to the parallel of all the other progressed during the four years from June 3, 1893 to 4, 1901 to 2, and 1909 to 10, and 1910 to 11.

72. The Graph Method—When the reader finds it rather embarassing to find all the secondary directions to parallel, he should draw a graph of the range of declinations of each body, marking the progressed dates on one side and the degrees of the declination on the other side of the graph. In the graph only the numerical variation in the declinations of each body should be shown, ignoring the names of the declinations. Every crossing of the graph lines of two bodies will show the date and the degree at parallel. Such a graph in George V's nativity for the 28 years from June 3, 1891 to June 3, 1919 would be as sketched below, in which the 25 parallels occuring during the period are shown as 25 circles, indicating the crossings.

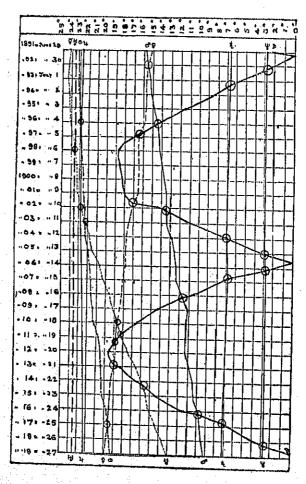

Fig. XVII—The graph showing the curves traced by the declinations of all the bodies during the 28 years from June 3, 1891, to June 3, 1912.

73. Are Progressed Horoscopes to be cast for Mean-time or Apparent time of birth?—As already observed meantime is a conventional affair, but apparent time is natural time. If the apparent time of birth is taken, as it ought to be, then the meantime equivalent of the apparent time of birth on a progressed date may differ from the meantime of birth on the birth-date. Hence, when the apparent time of birth is taken to cast progressed horoscopes, the time measured to will vary. But as secondary directions do not clinch correct to days, some are apt to ignore the point, and take the meantime of birth to cast progressed horoscopes, but precision requires us to go by apparent time.

LESSON X

PROGRESSION OF THE ANGLES

74. Can Progressed Angles be Directed ?-The zenith and the ascendant which are the Angles used, are fixed mundane points with no progression of their own, as they have no orbital revolution or annual motion. Nor could the ecliptic be held to progress, as it too has no orbital revolution. What is taken to be the progression of the angles is really due to diurnal rotation, a phenomenon which has no more to do with secondary directions than orbital revolution with primary directions. It is the practice to determine the angles at the birth moment on conscutive dates after birth, and to take the excess of longitude gained by them in one day as their daily motion. On this basis, the calculated arcs of directions are made to measure to a point of time in the corresponding progressed year. For example, in George V's nativity, progressed Ascendants on July 8 and 9, 1865, were 68° 59' and 70° 11'. So the daily motion of the Ascendant on the day is taken to be 70° 11′ - 68° 59′. i.e., 1° 12′. And when the progressed Ascendant appears to reach during the day the longitude 69° 11', that is, $12' \div 1/12$ of 1° 12' or two hours after the birth moment, calculating as if the ascendant progressed slowly and directly from 68° 59' to 69° 11', it is said to be in trine aspect to a radical whose longitude at birth was 309° 11'. The A.D. is said to be 69° 11'-68° 59', i.e., 12'. The time measured to by the arc is held to be $12' \div 1/12$ of 72', i.e., two months from the birth-date in the corresponding progressed year. Again, in regard to a progressed body whose progressed longitudes on July 8 and 9, 1865, were 158° 43' and 160° 19' respectively, the progressed ascendant is said to be in square aspect to the progressed body in the course of the day. For the two shorter distances are 89° 44' and 90° 8', and the extent 90° of the square aspect lies between them. The arc is said to be 16'. measured to by the arc is held to be 16' ÷ 1/12 of 24', i.e., 8 months from the birth-date in the corresponding progressed year. All this rests upon the assumption that the daily motion of the progressed Ascendant is 1° 12', that is, that it has progressed directly from 68° 59' to 70° 11' during the day. But it is by no means correct to take such a view. For, the ascendant has progressed really from 68° 59' to 360° 0' and from 0° to 70° 11' during the day, due to the diurnal rotation but not to annual motion. Consequently, its range of progress is from 68° 59' to 360° and from 0° to 70° 11', i.e., in all 361° 12'. Therefore, the progressed Ascendant could be directed during the day not only to the trine of the radical and to the square of the progressed body, but to the full cycle of 22

aspects, both of the increasing and the decreasing series, to these bodies and to all others. Hence, if progressed angles could possibly be directed at all, we have to take their daily motions to be about 361°, and their directions to all the twenty-two aspects and four parallels of every radical and progressed body resulting during a single progressed date and measuring to a single progressed year. Such an enormous number as, at least, 220 of its secondary directions to aspects of the radicals, and 44 to parallels of the radicals, and an almost equal number to the progressed bodies, all in one progressed date or progressed year, renders such directions to be of no value.

74. Can Progressed Angles be Directed to ?—Now, let us examine if progressed bodies could be directed to progressed angles. As the real daily motion of progressed angles is about 361°, they are vastly faster than the swiftest Moon. So none could be directed to them.

But it should be noted that progressed bodies could be directed to the radical angles, for radical angles are stationary points like all radical bodies, though radical angles could not be directed.

Contention IV - Angles cannot be Progressed.

LESSON XI

SIMPLIFIED SECONDARY DIRECTIONS

"Planets at Noon" Method-To cast progressed horoscopes, we take the birth-time on the progressed date, and find the positions of bodies by proportion from data given in ephemerides for Greenwich mean-noon. the labour of having to work several proportions of daily motions, what is known as the "Planets at Noon" or "P.A.N." method is adopted. In this method, the positions of bodies at the Greenwich mean-noon before or after the birthstime on the progressed dates are taken straight as they are, and entered in the maps for the respective progressed dates. As one day measures to one year, the positions at Greenwich mean-noon will measure to a proportionate point of time before or after the birth-date in the corresponding progressed year. For example, George V was born at 1-18. a.m., on June 3, 1865. In erecting his progressed maps, if we take the positions of bodies at the Greonwich mean-noon following the birth-time, then we should add to the birth-date in the progressed years, the period measured to by the advanced 12 hours minus I hour 18 minutes, i.e., 10 hours 42 minutes. As one day measures to one year, so one hour will measure to 15 days and one minute to one-fourth of a day. Therefore, 10 hours 42 minutes will measure to 163 days from June 3 in the progressed years, that is, to November This is known as the Noon Date. But if the positions of bodies at Greenwich mean-noon preceding the birth-time are taken, then we should count 202 days back from June 3, and we reach again November 12, the Noon Date. In this method, the period of time denoted by an arc of direction is counted onwards from the noon date. But while the positions of planets are taken as they were at the Greenwich mean-noons, the cusps are calculated for the birth-time itself. In the progressed map it is noted that the planets are as at noon of the progressed date measuring to the noon date in the progressed year, but that cusps are as at birth moment on the progressed date measuring to the birth-date in the progressed year. Some go a step further, as if to improve matters, and find the cusps also at the Greenwich mean-noon taken. But this is not done, as it ought to be done, by taking the sidereal time at the Greenwich mean-noon chosen for finding the positions of planets, but by adding to or deducting from the cusps at birth-time the proportionate value, taking that cusps progress only a few degrees in a day but not to about 361° odd as shown in Article 73. The reader is strongly urged not to spare himself a little honest labour to obtain a correct and vivid statement of facts, by adopting the usual method in preference to the P.A.N. method and its manipulations,

76. The Radical System—This is only a much simplified secondary direction to which no objection could be taken, as in the case of the P. A. N. method. Mr. Vivian E. Robson, B.Sc. has published a lucid exposition on the subject, which should be consulted by those desirous of learning the system.

PART III

LESSON XII

EPOCHAL ASPECTS

77. Epochal Aspects—Epochal Aspects are the zodiacal aspects formed at a particular epoch between two celestial bodies as they stood at the epoch. In all, the epochs adopted are five in number. (i) Synodical Lunation is the moment when the Sun and Moon stood after-birth date at the same relative distance from one another as at birth, for the ordinal number of time corresponding to the ordinal number of year of life in which a given date falls. (ii) Solar Revolution or Return is the moment just preceding a given date when the sun occupied the same longitude as at birth or at the moment of birth on the corresponding progressed date. (iii) Current Synodical Lunation is the moment just preceding a given date when the Sun and Moon stood at the same relative distance from one another as at birth. (iv) Lunar Revolution or Rotation is the moment just preceding a given date when Moon occupied the same longitude as at birth. And (v) Birth Map is for the moment of birth on a given date. The longitudes of the celestial bodies at each of these moments are determined in the usual way, and next the aspects subsisting between them, taking orbs (see Mathematical Astrology, Article 110) into consideration, are found. So there are no arcs of direction in the cases of the epochal aspects. These aspects are held to indicate incidents that are to be realised during the whole period between the epoch concerned and its succeeding one. So, there is no measurement of time in the case of epochal aspects. The new positions at an epoch are not referred to the radical or progressed positions of bodies as in directions, but only to the new positions of all other bodies at the same epoch.

We shall take three important dates in George V's life to determine on each date all the five epochal aspects, (i) July 6, 1893 when he was in his twenty-ninth year and married to the Queen, then Princess Mary, (ii) May 6, 1910 when he was in his forty-fifth year and his father Edward VII died, and he was proclaimed the king, and (iii) October 22, 1910 when he ascended the throne. Only problems relating to the second date will be fully worked out.

78. Synodical Lunation—A Synodical Lunation is the return of Moon after birth date to the same relative distance from the Sun, as it was at birth. It takes approximately 29'5 days for Moon to make a synodic return. As such, there are 12 synodic lunations in 354 days. At the birth of a child Moon will generally be at some distance, forwards or backwards from the Sun. Every 29'5 days after birth the synodical return of Moon to the same relative distance from the Sun that

it was at birth, takes place. It is held that the aspects subsisting between celestial bodies at a particular synodic lunation after birth, bear fruit in the same ordinal number of year of life as that of the synodic lunation. For example, at George V's birth Moon was 108° 37' 11" forwards from the Sun. This was the first synodic lunation, and the aspects between bodies subsisting at birth are held to have operated during the first year. The second synodic lunation when Moon was 108° 37' 11" forwards from the Sun, occurred at 6-41 p.m. G. M. T., on July 2, 1865; and so the aspects between bodies at 6-41 p.m. G. M. T., July 2, 1865, are held to bear fruit in the second year of life extending from June 3, 1866 to June 3, 1867. It will be evident that the epochal aspects at a synodical lunation are not strictly speaking epochal aspects as described in Article 77, but are intermediate between directional aspects and epochal aspects. For, they resemble directional aspects in bearing fruit at a remote period but not during the period immediately succeeding the epoch, as do the real epochal aspects; and they resemble the real epochal aspects in that they relate to the new positions of bodies at an epoch, but not to the radical or progressed positions of bodies as in directional aspects. So synodic lunations form a class by themselves.

79. Determination of all the Epochal Aspects on a given date—First find (1) the exact relative distance, correct to a second of arc, at which Moon stood from the Sun at birth, which is always obtained by deducting the Sun's adding 360° to Moon's previously longitude, longitude from Moon's longitude only when it is numerically less than that of the Sun (Dictum II). (2) The ordinal number of year containing the given date. (3) Then find the precise Greenwich mean-time on the date after birth, when Moon stood at the same relative distance from the Sun for the same number of time as the ordinal number of the year of life containing the given date. The approximate date of the synodical lunation is found by multiplying the ordinal number of lunation minus one by 29'5 days, and counting onwards from the date of birth and its precise moment by proportion from data found in an ephemeris for the date. (4) Now, determine in the usual way, the longitudes of all bodies at the precise G. M. T. on the date after birth, and the cusps at the precise L. M. T. of synodic lunation. Lastly, (5) determine all the epochal aspects at the synodic moment.

Problem 41—Find all the epochal aspects at the Synodic Lunation, relative to July 6, 1893, in George V's nativity.

Moon's longitude at birth was

181° 3′ 4″ 6°

72 25 53 6

∴ Moon was forwards from the Sun by

108 37 11 '0

July 6, 1893, fell after June 3, 1893, i.e., in the 29th year,

The twenty-ninth synodic lunation from birth occurred at $(29-1) \times 29.5$, i.e., 826 days after birth, i.e., on or about September 7, 1867.

> D's Long. ⊙'s. Long. For. Dist. of D Diff.

On 7-9-67 at G. M. N. 270° 0′ 59″1 164° 21′ 55%6 105° 39′ 3″5

6° 26′ 59′′′3

7/8-9-67 G.M. mid-night 276 57 7 2 164 51 112

.. The distance had to Moon gain at the synodic moment was 108° 37′ 11"'0 -105° 39′ 3″'5, i.e., 2° 58′ 7″'5.

The distance gained by Moon over the Sun in 12 hours was 6° 26′ 59″3.

.. 6° 26° 59"3; 2° 58' 7"5; 12 hours; hours from the G.M.N. of 7-9-67.

.. Dividing by 4, we have,

1° 36′ 44″ 9 : 0° 44′ 31″ 9 : : 3 hours : 4 ×

The terms of the ratio have to be divided by 4, to bring them within the compass of the Table of Ternary Proportional Logarithms. When the two terms of the first ratio are divided, the result obtained need not be multiplied by the divisor used, but when the third is divided, the result obtained should be multiplied by the divisor taken (see Mathematical Astrology, Articles 51 and 200).

.. (a.c.) 9'73037 + 0.60661 + 0'00000 = 0'33698, T. P. L. of I hr. 22 m. 51 s. *The synodic moment on September 7, 1867, when Moon was at the same forward distance of 108° 37′ 11" from the Sun was 1 hr. 22 m. 51 s. × 4 or 5 hr. 31m. 24 s. p.m. G.M.T. or 5 hr. 30 m. 47 s. L.M.T. on September 7, 1867, when the R. A. M. C. was 249° 1' 15". To test if the moment arrived at is correct, find the diurnal proportional arcs of the Sun and Moon for the odd period and apply it to their respective previous positions taken from the ephemeris, and see if Moon is forwards of the Sun by exactly the same distance. Having tested your result, cast the horoscope for G.M.T. 5 hr. 31 m. 24 s p.m., or L.M.T. 5 hr. 30 m, 47 s. p.m. on September 7, 1867. And now find all the epochal aspects including the parallel of declination between the several pairs of bodies.

Problem 42—Find all the epochal aspects at the Synodical Lunation, relative to May 6, 1910, in George V's nativity.

Moon was forwards from the Sun at birth by 108° 37' 11"'0.

May 6, 1910 fell in the 45th year of his life.

The 45th synodic lunation was $(45-1) \times 29^{\circ}5$ or 1298 days from birth, i.e., on or about December 22, 1868.

> D's Long. O's Long. For. Dist. of D. Diff.

And 4 times 0 hr. 41 m. 51s. = 2 hr. 47 m. 24s.

... The moment of the synodic lunation was 2 hr. 47 m. 24 s. p.m. G.M.T. or 2-46.47 L.M.T. on January 22, 1869, when the R.A.M.C. 343° 41′ 0″. Now cast the horoscope for the G.M.T. 2 hr. 47 m. 24 s. p.m., i.e., L.M.T. 2-46-47 p.m. And now find all the epochal aspects including the parallel of declination.

80. Solar Revolution or Return—Solar Revolution is the return of the Sun to the same longitude as it was at birth. This occurs once in a year about the

birth-day. It is held that the aspects subsisting between colestial bodies at the moment when the Sun occupies the same longitude as at birth, operate during the year succeeding the moment. For example, at George V's birth the Sun was at 72° 25′ 53"6, and the effects of the aspects subsisting at the moment in every year when the Sun was at 72° 25' 53".6, are said to be felt during the whole year succeeding the moment. It will not do to take the Sun's longitude at birth correct to a minute of arc, but it should be taken correct to a second of arc or even to one. tenth of a second of arc. For, if the longitude is taken correct to a minute of arc. an error of one minute in the Sun's longitude will cause an error of about 24 minutes of time, as Sun moves approximately 60 minutes of arc in one day or 1440 minutes of time, and an error of 24 minutes of time will produce an error of about 14 minutes of arc in Moon's longitude, and about 6 degrees in the longitudes of the cusps. The approximate moment of return is readily found from an ephemeris: and the precise moment by proportion as usual. The map of the heavens erected for the moment of the solar revolution or return in a year is also known as the birth-day map; for the solar returns take place usually about the birth-date in every year. The aspects bear fruit during the year extending from one solar return to the next.

Problem 44—Find all the epochal aspects at the Solar Revolution, relative to July 6, 1893, in George V's nativity.

The longitude of the Sun at birth was 72° 25' 53"'6.

July 6, 1893, fell in the 29th year measuring from June 3, 1893.

.. The solar return was on or about June 3, 1893.

O's. Long.

Problem 46-Find all the epochal aspects at the Solar Revolution, relative to October 22, 1910, in George V's nativity.

The longitude of the Sun at birth was 72° 25′ 53"6.

October 22, 1910, fell in the 46th year measuring from June 3, 1910.

.. The solar return was on or about June 3, 1910.

A & & |

3-6-1910 G.M.N.	⊙'s. Long. 72° 0′ 37′″4	Daily motion.
4-5-1910 G.M.N.	72 58 5 0	0° 57′ 27″ 6

The Sun had to gain 72° 25′ 53″6-72° 0′ 37″4, i.e., 0° 25′ 16″2.

:.0 °57' 27"'6: 0° 25' 16"'2:: 24 hours: No. of hours from G.M.N. 3-6-10.

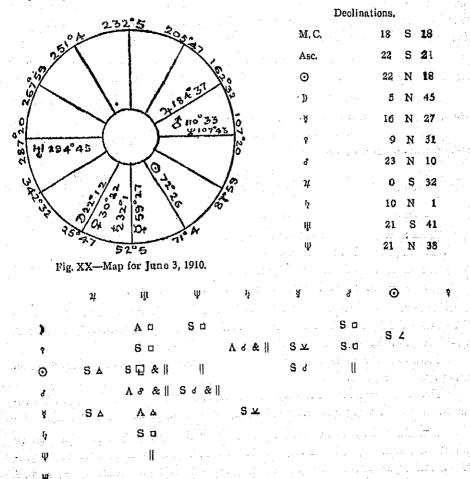

Dividing the third term by 8, we get,

9'50409 + 0'85266 + 0'00000 = 0'35675, T.P.L. of 1 hr. 19 m. 9'8 s.

And 8 times 1 hr. 19 m? 9.8 s = 10 hr. 33 m. 184 s.

The solar return was at 10 hr. 33 m. 18 s. p.m., G.M.T., or 10-32-41 p.m., L.M.T. on June 3, 1910, when R.A.M.C. was 229° 40′ 0″.

Now cast the horoscope for G.M.T. 10-33-18 p.m. or L.M.T. 10-32-41 p.m., on June 3, 1910. And now find all the epochal aspects.

81. Solar Return to the Progressed Sun—According to some, the moment when the Sun returns to its longitude on the progressed date corresponding to the year of the give date, instead of to the longitude of the radical Sun as in Article 80, is taken. For, the Sun while he completes the ecliptic circle in one year, does not move through 360° with reference to a place, but does so only when he has moved through 361° ecliptic degrees. In other words, it is only after one year and one day, that the Sun returns to the same mundane position after birth. The horoscope for the moment of the solar return to the progressed longitude of the Sun is cast, and all the epochal aspects are determined. If this system is adopted, then a progressed day will measure not to one year but to one year and one day; and consequently the anniversary of birth will not fall on the date of birth in every year but one day after birth for every subsequent year. These aspects are held to bear fruit during the year and one day from the solar return to one progressed position to the solar return to the succeeding progressed position.

Problem 47—Find all the epochal aspects at the moment of Solar Return to the progressed longitude of the Sun, relative to July 6, 1893, in George V's nativity.

July 6, 1893 fell after the twenty-ninth birth-date, June 3, 1893, and the twenty-ninth progressed date is July 1, 1865.

The Sun's longitude at the A.T. of birth, i.e., at 13 hr. 23 m. 39 s. or 1-24 a.m. G.M.T. on July 1, 1865, was 99° 9′ 55″.

The Sun had to gain 99° 9′ 55″ - 98° 51′ 5″, i.e., 0° 18′ 50″.

.. 57' 11": 18' 50": 24 hours: No. of hours from G.M.N. of 30-6-1893. Dividing the third term by 8, we have, 9'50200+'98035=0'48235, T.P.L. of 0 hr. 59 m. 17'1 s.

The moment of Solar Return to its longitude on the corresponding progressed date was 7 hr. 54 m. 17 s. after G.M.N. on 30.6.1893, i.e., 7-54-17 p.m. G.M.T. or 7-53-40 p.m. L.M.T., when the R.A,M.C. was 217° 30′ 45″.

Now cast the horoscope for the moment of return on June 30, 1893, and find

Problem 48—Find all the epochal aspects at the Solar Return to the Progressed longitude of the Sun, relative to May 6, 1910, in George V's nativity.

The Sun's longitude at the A.T. of birth on the 45th progressed date, i.e., at G.M.T. 1-26 a.m. on July 17, 1865, was 114° 25′ 14″. The Sun returned to the proposed longitude, 114° 25′ 14″, in the 45th year at 4-46-15 p.m. G.M.T., i.e., 4-45-38 p.m. L.M.T. on July 17, 1909, when the R.A.M.C. was 186° 16′ 15″.

Now cast the horoscope for the moment of return on July 17, 1909, and find all the epochal aspects.

Problem 49—Find all the epochal aspects at the Solar Return to the Progressed longitude of the Sun, relative to October 22, 1910, in George V's nativity.

The Sun's longitude at the A.T. of birth on the 46th progressed date, i.e., at 1-26 a.m. G.M.T., on July 18, 1865 was 115° 22′ 29″. The Sun returned to the progressed longitude, 115° 22′ 29″, at 10-24-0 p.m. G.M.T. or 10-23-23 p.m. L.M.T. on July 18, 1910, when the R.A.M.C. was 271° 41′ 15″.

Now cast the horoscope for the moment of Solar Return on July 18, 1910, and find all the epochal aspects.

It may be observed that the validity of Solar Return to the progressed longitude is questionable. For example, if Problem 48 is worked out, and the aspects will be found not quite significant as compared with those given in the corresponding Problem 45.

- 82. Current Synodical Lunations—Current Synodical Lunations are those just preceding a given date. So when a date is given we should ascertain the moment just previous to it, at which moon was at the same relative distance from the Sun as at birth. The effect of the aspects formed at the moment are viewed to be realised during the synodic month of 29'5 days from the moment. These returns are called current synodical lunations, to distinguish them from the lunation described in Article 79.
- 83. Determination of all the aspects at a Current Synodical Lunation-A Synodical Lunation occurs once in 29'5 days, and so Moon gains in elongation on on an average 12° daily. Always we want to know the moment of the just previous synodic lunation. So we should find (i) the distance of Moon from the Sun at birth, and (ii) the date and the precise G.M.T. of the synodic lunation just previous to the given date. The former is easily found as usual, by deducting the Sun's longitude at birth from Moon's longitude at birth, applying Dictum II when necessary. To find the latter we should ascertain the distance of Moon from the Sun at G.M.N. on the given date by subtracting the Sun's longitude from Moon's, adding 360° to Moon's position if it is numerically less (Dictum II), and taking the difference with no rectification, as the distance from the Sun to Moon on the date. Next, divide the distances at birth and at G.M.N. on the given date, both taken correct to a degree by 12, to find the Age of Moon in days. The Age of Moon on the given date may be greater or less than its age at birth, the maximum Age of Moon, taken approximately, is 30 days. When the Age of Moon on the given date is greater, the difference between the two ages gives the number of days we have to count back from the given date to reach the day of the previous synodic lunation : and when the Age of Moon on the given date is less, add 30 to it and deduct the

Age of Moon at birth, and with the number of days obtained count back from the given date to get at the day of the previous lunation. Now, take an ephemeris for the year and find the positions of the Sun and Moon on the date counted back, and ascertain the precise moment of the synodic lunation, and cast the horoscope for the moment of synodic lunation, and find all the aspects subsisting at the moment.

Problem 50—Find all the epochal aspects at the Current Synodical Lunation, relative to July 6, 1893, in George V's nativity.

At birth the distance from the Sun to Moon was 108° 37′ 11″'0, i.e., the approximate Age of Moon was 9 days.

At G.M.N. on July 6, 1893, the approximate distance from the Sun to Moon was 360°+9°-104°, i.e., 265°, and so Moon's Age was 22 days. On the given date Moon is older than at birth. So counting back 22-9, i.e., 13 days from July 6, 1893, we reach June 23, 1893.

On reference to an ephemeris for 1893 we find the following data:-

22-6-1893 G.M.N. 197° 5′ 50″ 5 91° 13′ 31″ 8 105° 52′ 18″ 7

22 6-1893 G.M.N. 5° 34′ 46″ 2

22-6-1893 G.M.M. 203 9 13 2 91 42 8 3 111 27 4 9

The distance Moon had to gain was 108° 37' 11"-105° 52' 18"7, i.e., 2° 44' 52"'3.

.. 5° 34′ 46″2; 2° 44′ 52″3; 12 hours; No. of hours from G.M.N. of 22-6-93.

Dividing all the terms by 4, we have,

9'667441 + 0'64019 + 0'00000 = 0'30760, T.P.L., of 1 hr. 28 m. 38'9 s.

4 times 1 hr. 28 m. 38'9 s. is 5 hr. 54 m. 35 s.

.. The moment of the previous current synodic lunation was 5-54-35 p.m. G.M.T. or 5-53-58 p.m. L.MT., on June 22, 1893, when the R.A.M.C. was 179° 37' 45".

Now cast the horoscope for 5-55 p.m. G.M.T., i.e., 5-53-58 p.m. L.M.T. on June 22, 1893, and find all the epochal aspects.

Problem 51—Find all the epochal aspects at the Current Synodical Lunation, relative to May 6, 1910 in George V's nativity.

At birth the approximate Age of Moon was 9 days.

At G.M.N. on May 6, 1910 the approximate distance from the Sun to Moon was 360° + 7° - 45°, i.e., 322°, and so Moon's age was 27 days. On the given date Moon was older than at birth, so counting back 27 - 9, i.e., 18 days from May 6, 1910, we reach April 18, 1910.

On reference to an ephemeris for 1910, we find the following data:

D's Long. O's Long. Distance. Diff.

17/18-4-10 G.M.M. 134° 0' 43"'8 27° 4' 51"'4 106° 55' 52"'4

5° 50′ 16″'7

18-4-10 G.M.N. 140 20 I9 '2 23 34 30 '1 112 46 9 '1

The distance Moon had to gain was 108° 37′ 11" - 106° 55′ 52"'4, i.e., 1° 41′ 18"'6.

.. 5° 50′ 16′′′7: 1° 41′ 18′′′6:: 12 hours: No. of hours from G.M.M. of 13/18-4-10.

Dividing all the terms by 4, we have,

9'687084+0'851681+0'000000=0'538765, T.P.L. of 0 hr. 52 m. 3'6 s.

4 times 0 hr. 52 m. 3'6 s. is 3 hr. 28 m. 4 s.

The moment of the previous current synodic lunation was 3-28-14 a.m. G.M.T. or 3-27-37 a.m. L.M.T. on April 18, 1910, when the R.A.M.C. was 257° 16′ 30″.

Now cast the horoscope for 3-28 a.m. G.M.T., i.e., 3-27-37 a.m. L.M.T. on April 18, 1910, and find all the epochal aspects.

Problem 52—Find all the epochal aspects at the Current Synodical Lunation, relative to October 22, 1910, in George V's nativity.

At birth the approximate Age of Moon was 9 days.

At G.M.N. on October 22, 1910, the approximate distance from the Sun to Moon was $360^{\circ}+83^{\circ}-208^{\circ}$, i.e., 235°, and so Moon's age was $235\div12$, i.e., 19 days.

On the given date Moon was older than at birth, so counting back 19-9, i.e., 10 days from October 22, 1910, we reach October 12, 1910.

D's Long. O's Long. Distance. Diff. 12/13-4-10 G.M.M. 305° 25′ 8″6 198° 46′ 38″9 106° 38′ 29″7

6° 0′ 12′ 3

13-4-10 G.M.N. 311 55 3 '2 199 16 21 '2 112 38 42 '0

The distance Moon had to gain was 108° 37′ 11″ - 106° 38′ 29″ 7, i.e., 1° 58′ 41″ 3.

∴6° 0′ 12″3: 1° 58′ 41″3: 12 hours: No. of hours from G.M.N. of 12/13-4-10.

Dividing all the terms by 4, we have,

9'69922+'78292+0'00000=0'48214, T.P.L. of 0 hr. 59 m. 18'7 s.

4 times 0 hr. 59 m. 187 s is 3 hr. 57 m. 15 s.

.. The moment of the previous current synodic lunation was 3-57-15 a.m. G.M.T., i.e., 3-56-38 a.m. L.M.T. on October 13, 1910, when the R.A.M.C. was 79° 59′ 30″.

Now cast the horoscope for 3-57 a.m. G.M.T., i.e., 3-56-38 a.m. L.M.T. on October 13, 1910, and find all the epochal aspects.

84. Lunar Revolutions or Returns—Lunar Revolution is the return of Moon to the same longitude as it was at birth. This occurs once in about 27 days. It is held that the aspects subsisting between bodies at the moment when Moon occupies the same longitude as at birth, bear fruit during the lunar month of 27 days succeeding the moment of return. For example, at George V's birth the longitude of Moon was 181° 3′ 4″6, and the effects of the aspects subsisting at every lunar return, i.e., after about every 27 days from birth, are said to be felt during the 27 days succeeding the moment of return. The longitude of Moon may be taken correct to a minute of arc, for the difference of one minute of arc in the Moon's position will produce only an error of only two minutes of time. The approximate moment of return is readily found from an ephemeris: and the precise moment is found by proportion as usual. The map erected for the moment of Lunar Return is also known as the monthly map.

Problem 53—Find all the epochal aspects at the Lunar Return just prior to July 6, 1893, in George V's nativity.

The longitude of Moon at birth was 181° 3' 4"6.

Just prior to July 6, 1893, Moon returned to its longitude at birth between the Greenwich mean mid-night on June 20/21, 1893, and G.M.N. on June 21, 1893.

) 's Longitude.

Motion during 12 hours.

20/21-6-93 G.M. mid-night

Moon had to advance 181° 3' 4"6-178° 43' 53"0, i.e., 2° 19' 11"6.

∴6° 10′ 11″6: 2° 19′ 11″6:: 12 hours; No. of hours from the G.M.N.

Dividing all the terms by 4, we have,

9'71109 + 0.71371 + 0'00000 = 0'42480, T.P.L. of 1 hr. 7 m. 40'9 s.

4 times 1 hr. 7 m. 40'9 s is 4 hr. 30 m. 43'6 s.

. The Lunar Return was at G.M.T. 4-30-44 p.m. or L.M.T. 4-30-7 p.m. on October 2, 1910, when the R.A.M.C. was 258° 2′ 15″.

Now cast the horoscope for the moment, and find all the epochal aspects.

86. Diurnal Map—Diurnal Map is the one cast for the moment of birth on a given date. Usually the mean-time of birth is taken. According to some, the apparent time of birth (see Article 72) on every day is taken, and its mean-time

equivalent is found, and the horoscope is cast for it. We shall adopt the latter view. The aspects subsisting at the moment of birth on every day is held to portend events to transpire during the day.

Problem 56—Find all the epochal aspects at the Moment of Birth on July 6, 1893, in George V's nativity.

The G.M.T. of birth was 1.18 a.m.

The L.M.T. of birth was 1-17-23 a.m.

The Equation of time on the date, as applied to mean-time, was +2 m. 13 s. : Local Apparent time of birth was 1-19-36 a.m.

The Equation of time, as applied to apparent time, at the midnight of July 5/6 was +4 m. 26 s.

.. The L.M.T. of birth on July 6, 1893, was 1-24-2 a.m., and the G.M.T. was 1-24-39 a.m., when the R.A.M.C. was 305° 16′ 0″.

Now cast the horoscope for the moment, and find all the epochal aspects.

Problem 57—Find all the epochal aspects at the Moment of Birth on May 6, 1910, in George V's nativity.

The Local Apparent time of birth was 1-19-36 a.m.

The Eq. of time as applied to apparent time at G.M. midnight on May 5/6, 1910 was -3 m. 25 s.

. The L.M.T. of birth on May 6, 1910, was 1-16-11 a.m., and the G.M.T. was 1-16-48 a.m., when the R.A.M.C. was 242° 4′ 0″.

Now cast the horoscope for the moment, and find all the epochal aspects.

Problem 58—Find all the epochal aspects at the Moment of Birth on October 22, 1910, in George V's nativity.

The Local Apparent time of birth was 1-19-36 a.m.

The Eq. of time as applied to apparent time at G.M. midnight on October 22/23, 1910, was -15 m. 17 s.

The L.M.T. of birth on October 22, 1910, was 1-4-19 a.m., or the G.M.T. was 1-4-56 a.m., when the R.A.M.C. was 45° 40′ 0″.

Now cast the horoscope for the moment, and find all the epochal aspects.

PART IV

CURRENT ASPECTS

LESSON XIII

TRANSITS

Transits-Transits are current aspects formed between the current positions of bodies and the radical or progressed positions of bodies and angles. A transit is the passage of a body over the radical or progressed positions of bodies The passage of a body over the point opposite to a radical or proand angles. gressed position is also regarded to be a transit. So transits are conjunctions or In order to differentiate these conjunctions and oppositions from the oppositions. ordinary ones, they are termed conjunctions by transit, and oppositions by transit. Transits by the square and by the trine are adopted by some, but are of subordinate value; and transits by the other aspects are held to be too feeble to deserve So, we have only four aspects to be noted in transits. The radical or progressed position passed over by a body is said to be the transitted point or significator. Of the four angles and the nine bodies only the two angles, the Mid-heavens and the Ascendant, and the two luminaries, the Sun and Moon, are universally held to be the four important significators, and the remaining seven planets are taken to be significators of minor value. The body passing over a radical or progressed position is the transitting body or promittor or exciter, and it may be any one of the nine bodies. Jupiter, Saturn, Uranus and Neptune being tardy in motion, their transits over the significators last for a long period, and as such are viewed to be telling promittors: Mars being a body with considerable velocity, its transits are less lasting than the former, but decisive, and so important: Moon, Mercury, Venus and the Sun being quickly moving bodies, their transits are ephemeral, lasting only a few hours as in the case of Moon, or a few days as in the case of the But the transits of the luminaries, the Sun and Moon, are held to be very effective, especially when they pass through the houses of a horoscope. To sum up, the transits of Mars, Jupiter, Saturn, Uranus and Neptune by conjunction, opposition, square and trine over the radical or the progressed positions of the four essential significators, the Mid-heavens, the Ascendant, the Sun and Moon, are the only important transits to be determined.

Transits include also the New Moons, the Full Moons, and the Eclipses. New Moon or Moon when in conjunction with the Sun, and Full Moon or Moon when in

opposition to the Sun, are held to be very important transits. Always Solar Eclipses occur at a New Moon, and Lunar Eclipses at a Full Moon. So eclipses are also transits which are still more important than the ordinary New and Full Moons.

88. Determination of Transits at a given time—We have first to find the positions of Conjunction, Opposition, Square and Trine with the two angles and the two luminaries in particular, both at birth and at the moment of birth on the progressed date corresponding to the given time. These positions of each set of radicals and of the progressed may be arranged separately in their numerically increasing order, to facilitate the spotting of transits. Next, the range of positions of all the nine bodies during the given period should be noted.

The given period may be one day or any longer period. The range of the positions of a body during a period are its positions at the Greenwich mean-midnights at the beginning and at the end of the period. Record also all Eclipses, New Moons, and Full Moons transpiring during the given period. This is generally done with the help of an ephemeris for the given time. Now all coincidences of the current positions of the nine bodies with the radical and progressed positions of the four aspects to the two angles and the two luminaries are noted as transits. example, if we want to ascertain all the transits that operated in the 45th year of George V's life, that is, from June 3, 1909 to June 3, 1910, we take (i) the positions of the two angles and the two luminaries at birth, and (ii) their positions at the apparent moment of birth on the corresponding progressed date, i.e., 1 26 a.m. 'G.M.T. on July 17, 1865. To each of these positions of either set, we add and subtract in succession the aspect extents of Conjunction, Square, Trine and Opposition, i.e., 0°, 90°, 120° and 180°, to find the corresponding aspects by transit both of the decreasing and the increasing series Next, the aspect positions of each set are arranged in their numerically increasing order. Lastly, refer to the ephe merides for 1909 and 1910, and take the range of longitudes passed through during the year June 3, 1909 to June 3, 1910 by each of the nine bodies. In transits over the Radicals the range of positions is the one from the position at the Greenwich mean-midnight on June 3, 1909 to the position at the Greenwich mean midnight on June 3, 1910 · and in the case of transits over the Progressed places, it is that from the midnight of July 17, 1909 to July 18, 1910. Now, spot all coincidences between the aspect positions and the current positions of each set, radical or progressed. The concurrences so marked off will be the Transits. In determining Transits, an orb of one or two degrees is usually allowed. Also note the radical and the progressed houses of a horoscope passed through by each body. Echipses, New Moons and Full Moons can be found from the aspectarian given in an ephemeris. Therefore, we should have two schedules prepared in regard to the aspect positions of (i) the Radicals and (ii) the Progressed. The schedule of the radical positions

and their aspects, no matter what the date may be, will be the same; but the schedule of the progressed positions and their aspects, will vary with each progressed date, and so a separate one should be prepared for each progressed date. For example, in George V's nativity Schedule XXI of the Radicals and their aspects will hold true for all given dates, but Schedules XXII, XXIII and XXIV of the Progressed positions and their aspects will relate to the three different dates selected, e.g., July 6, 1893, May 6, 1910, and October 22, 1910.

The Radicals and their Aspects.

·	Conjunction	Square	Trine	Opposition
Asc.	2° 3′	92° 3′ 272 3	122° 3′ 242 3	182° 3′
Ψ	10 10	100 10 280 10	130 10 250 10	190 10

Problem 59—Find all the transits over the radicals, relative to July 6, 1893, in George V's nativity.

The range of the current positions of the bodies from midnight to midnight on July 6, 1893, and their transits of houses were as:—

			•			Transits							T	ransits
D	2°	35′	to	16°	6′	XII and I	4	53°	17′	to	53°	30′		II
0	104	6	to	105	3	IV	l ⁵	186	40	to	186	42		VII
ğ	129	52	to	131	3	V	ı́Н		21	6	39			VII
₽.	121	31	to	122	44	V	Ψ	72	15	to	72	17	•	II
₫	123	42	to	124	19	V								

On comparing these current positions with the aspect positions in Schedule XXI, we find the following transits over bodies:—

))	ઇ	Λs	c.	r	9	Δ	As	c. r
D	Δ	ð	r		ð	Δ	As	c. r
D	ડ	ψ	r		3	ď	ð	r
ų 1	a	Ŷ	r		ij		ð	r
ğ	Δ	ψ	r		Ψ	ď	Ō	r

New Moon was on June 14, 1893, when the longitude of Moon was 83° 21′, $D \triangle P$ r. Full Moon was on June 29, 1893, when the longitude of Moon was 277° 40′, $D \triangle P$ r.

Problem 60—Find all the transits over the radicals, relative to May 6, 1910, in George V's nativity.

The range of the current positions of bodies, from midnight to midnights on May 6, 1910, and their transits of houses were as follows:—

						Transits							Transits
D	359°	12'	to	14°	0′	XII and I	2/	185°	41′	to	185°	36′	VII
0	44	35	to	45	33	I	12	28	38	to	28	45	I
À	64	53	to	65	32	II	ıĤ		2	95	13		ΧI
ę	358	52	to	359	54	XII	Ψ		10	96	57		IV
ð	92	34	to	93	11	IV	• .						

On comparing these current positions with the aspect positions in Schedule XXI, we find the following transits over bodies:—

D 🖂 M	r		D	ď	Ψr
D M.O	C r		· •		Шr
D & D	r		ę	Cl	M.C. r
Dod Aso	3. X		♂		Asc. r
D A &	r		ų	П	4 r

New Moon and Solar Eclipse was on May 9, 1910, when the longitude of Moon was 47° 42′, D & Y r. Full Moon and Lunar Eclipse was on May 24, 1910, when the longitude of Moon was 242° 10′, D \(\text{Asc. r.} \)

Problem 61—Find all the transits over the radicals, relative to October 22, 1910, in George V's nativity.

The range of the current positions of bodies from midnight to midnight on October 22, 1910, and their transits of houses were as follows:—

<i>i</i>						Transits							Transits
D	75°	13'	to	89°	42'	III	24	205°	33′	to	205°	46′	. VII
0	207	43	to	208	42	VII	ι ⁵	33	32	to	33	27	Ι
¥.	193	48	to	195	25	VII	IţI		29	1	27 .		ΧI
2	198	48	to	200	3	VII	φ		11	1	34		IV
• &	199	39	to	200	18	VII							

On comparing these current positions with the aspect positions in Schedule XXI, we find the following transits over bodies:—

) A	þ r			Θ, Δ	Щr
D &	4 r	•	•	ŞΔ	0 r,
D q	₩ r	- 1.		4. ď	'n r
D 8	M.C. r				ďŢ.

New Moon was on October 3, 1910, when the longitude of Moon was 189° 15', D ε Ψ r. Full Moon was on October 18, 1910, when the longitude of Moon was 24° 20', D ε η r.

Now let us take the progressed bodies and their aspects on the three dates.

(i) July 6, 1893—the previous birth-date was June 3, 1893. Progressed date July 1, 1865. The equivalent moment of birth on July 1, 1865, was 1-23 a m. G.M.T.

The positions and their aspects at 1-23 a.m. G.M.T. on July 1, 1865, were as follows:—

	Conjunction	Square	Trine	Opposition
Ψ	10° 34′	100° 34′ 280 34	130° 34′ 250 34	190° 34′
•	54 41	144 41 324 41	174 41 294 41	234 41
Asc.	59 6	149 6 329 6	179 .6 299 6	239 6

	Conjunction	Square	Trine	Opposition
ιfī	90° 18′	180° 18′ 0 18	210° 18′ 330 18	270° 18′
¥	98 12	188 12 8 12	218 12 338 12	278 12
• ⊙	99 10	189 10 9 10	219 10 339 10	279 10
đ.	142 17	232 17 52 17	262 17 22 17	322 17
D	189 1	279 1 99 1	309 1 69 1	9 1
Į5	203 37	293 37 113 37	323 37 83 37	23 37
4	262 10	352 10 172 10	22 10 142 10	82 10
M.C.	297 47	27 47 207 47	57 47 177 47	117 47

Now arranging these positions in their numerically increasing order, we get the following schedule:—

Schedule XXII-The Progressed bodies and Aspects for the 29th year.

Progressed position	Aspect		Progressed	position	Aspect

Problem 62—Find all the Transits over the progressed bodies, relative to July 6, 1893, in George V's nativity.

The range of the current positions of bodies, from midnight to midnight, on July 6, 1893, (see Problem 59) and the transits of houses were as follows:—

Transits						-	Transits
D 2° 35′ to 16° 6′ XII	4	53°	17′	to	53°	30′	
© 104 6 to 105 3 III ¥ 129 52 to 131 3 IV	Į5	186	40	to	186	42	VI
121 31 to 122 44 IV	ıÎt				39		VI
3 123 42 to 124 19 IV	ψ	72	15	to	72	17	I

On comparing the current positions with the aspect positions in Schedule XXII, we find the following transits over progressed bodies:—

D		Ą	p				
			A Control of the State of the Control of the Contro	4	O	đ	p
			P	ħ	D	¥	n
D		.0	p			٠.	
9.0		4.75	P	Ħ	Δ	¥	р
** **				Ψ	Д	D	
À	Δ	Ψ.				-	۳.

For New and Full Moons see under Problem 59,

(ii) May 6, 1910—the previous birth-date was June 3, 1909. The Progressed date was July 17, 1865, and the equivalent moment of birth was 1-26 a.m. G.M.T.

The positions and their aspects at 1-26 a.m. G.M.T. on July 17, 1865 were as follows:—

				•
٠	Conjunction	Square	Trine	Opposition
Ψ	10° 35′	100° 35′ 280 35	130° 35′ 250 35	190° 35′

Problem 64—Find all the Transits over progressed bodies, relative to October 22, 1910 in George V's nativity.

The range of the current positions of bodies from mid-night to mid-night on October 22, 1910 (Problem 61) and Transits our houses were as follows:—

		Transits	•	Transits
D	75° 13′ to 89° 42′	XII & I Prog. 4	205° 33' to 205° 46'	V Prog.
0	207 43 to 208 42	V ,	33 32 to 33 27	XII
Ą	193 48 to 195 25	V "	291 27	VIII
å	198 48 to 200 3	Vψ	111 34	TI ·
3	199 39 to 200 18	V		

On comparing the current positions with the aspect positions in Schedule XXIV, we find the following transits our bodies.

D	Δ M.C. p	•	\$	۵	Asc. p
Ð	d Asc. p		ď	Δ	Asc, p
D	8, 4 p		24	O	Θp
Þ	$\Delta = \frac{t_2}{2} - p$		I2	۵,	d b
¥	Δ M.C. p				

For New and Full Moons see under Problem 61.

Schedule XXV-Recapitulation of the characteristic features of each class of Directions and Aspects.

	Isthere an orb?	i A	No.	No	Yes	Yes	No	No No	No	Yes
especta-	Is there an arc of direction?	Z	Yes	Yes	o'N	No	No	No	No	No
was a Lucaions and rispects	When Directions or Aspects bear fruit	Whole life	During the year measured to by the	During the ordinal year corresponding to the ordinal number of day from birth on the Procressed date	During the ordinal year of life corresponding to the ordinal number of the lunation from birth	During the whole year succeeding the moment	During the whole synodic month succeeding the moment	During the whole lunar month succeed-	During the whole	During the period of Transit
	Bodies in Aspect	Radicals	Radicals and bodies soon after birth	Progressed bodies at the moment and Radicals or other Pro- gressed bodies at the moment	Bodies at the moment	Bodies at the moment	Bodies at the moment	Bodies at the moment	Bodies at the moment	Radicals or Progressed, and Bodies during the period
	Nature of Aspects	Zod. & Mund.	Mundane (and Zodiacal)	Zodiaca1	Zodiaca i	Zodiacal	Zodiacal	Zodiacal	Zodiaca1	Zodiacal
	The Moment for Casting the horoscope	The moment of birth	The moment of birth	The equivalent moment of birth on the same ordinal date subsequent to birth as the ordinal number of year of life	The moment when Moon was at the same distance from the Sun as at birth, for the same number of time as the ordinal number of year of life containing the given date	The moment just before the given date when the Sun was at the same longitude as at birth	The moment just before the given date when Moon was at the same distance from the Sun as at birth	The moment just before the given date when Moon was at the same longitude as at birth	The equivalent moment of birth on the given date	The Greenwich mean-midnights both at the beginning and at the end of the given period
	Directions or Aspects	Radical Aspects	Primary Direction	Secondary Direction	Synodic Lunation	Solar Return	Current Synodic Lunation	Lunar Return	Гар	Transit

- 89. Comparative Study of Aspects and Directions—Let us take the three most important dates in George V's life, namely, July 6, 1893, May 6, 1910 and October 22, 1910, and see what are the several aspects, directions and transits that have had a bearing on his life on the dates. We have to note the aspects, directions and transits relative to these different dates under the following heads:—
 - (i) All the Radical Zodiacal Aspects.
 - (ii) All the Radical Mundane Aspects.
 - (iii) All the Primary Mundane Directions relative to the 29th, the 45th and the 46th year.
 - (iv) All the Secondary directions of the progressed to the radicals, and of the progressed to the other progressed bodies, relative to the three years.
 - (v) The Epochal Aspects at the Solar Returns at the beginnings of the three years.
 - (vi) All Transits over the radicals and the progressed bodies during the three days. `

Though the arcs of primary mundane directions are strictly speaking only about 28° 5′, 44° 55′ and 45° 20′, yet we shall take into consideration also directions whose arcs are half of a degree more or less. In the case of secondary directions we shall take directions whose arcs measure to six months before and after the dates.

INDEX

N.B.—The figures refer to pages.

λ

Admissibility of Converse Directions, 9, Angles, Can Progressed—be directed? 96; Can Progressed—be directed to? 97.

Angular or Aspect Extent (A.E.), 6. Answers, 134-160.

Anti-clockwise and Clockwise Distances from D.B. to S.P., 12.

Arc of Direction (A.D.), 17, 40.

Aspect Angle, First—and the Subsequent Ones, 55.

Aspects and Directions, Comparative Study of—, 129.

Aspects, Epochal—, 100; Mundane—5; —of Direction, 6;—Zodiacal—, 5.

Aspect Extents of Direction, Scale of—, 16.

В

Birth-day Map, 104.
Bodies, Mundane Positions of—, 2;
Progressed—, 73; Radical—, 73.
Body, Directed—, 6, 47; Passive—, 47;
Transitting—, 115.

n

Casses, I & II of Primary Mundane Directions, 15;—A, B, C & D of Isolated Primary Mundane Directions, 30, 33;—1, 2, 3 & 4 of both Types 1 and 2 of Mundane Parallels, 43;—(i) and (ii) of Rapt Parallels, 49 to 51.

Classification of Directions, 6. Clockwise and Anti-clockwise Distances from D.B. to S.P., 12.

Combined Mundane Map, 3.

Comparative Study of Aspects and Directions, 129.

Conjunction by Transit, 115.

Contention I—Converse Directions are inadmissible, 10.

Contention II—Directions to the Horizon are needless, 36.

Contention III—Primary Zodiacal Directions are irrational, 69.

Contention IV—Angles cannot be Progressed, 97.

Converse Directions, 7, 54; Admissibility of—, 9,

Correction, of the Arc of Direction for the Annual Motion of the Directed Body, 70; Negative and Positive—, 70.

Current Synodical Lunations, 109; Determination of all the Aspects at a--, 109.

Cuspal Distance, Backwards, 3;—Forwards, 3.

D

Date, Progressed—Corresponding to an Ordinal Year of Life, 74; Noon—, 99. Decreasing and Increasing Series of Aspects of Direction, 15.

Determination of, the A.D. of a Body directed to a given Aspect, 30;—A.D.'s in a series of Primary Mundane Directions, 20;—A.D.'s in the Mundane Parallels of all bodies to different S.P.'s, 46;—all Rapt Parallels, 51;—all the Aspects at a Current Synodical Lunation, 109;—all Epochal Aspects on a given date, 101;—Arc of Direction, 81, 88;—Correction for the Annual Motion of a Directed Body, 70;—Mundane Aspect of a given A.D., 33;—Transits at a given time, 116.

Dictum I—The Taking of Arcs, 13.
" II—The Rectification of Arcs, 15.

,, III—The Subtraction of Angles,

Different Types of Mundane Parallels, 37.

Direct Body and Passive Body, 47.

Directed Body (D.B.), 6.

Directions, 6; Admissibilary of Converse—, 9; Arcs of—, 17; 40, 49; Classification of—, 6; Direct and Converse—, 54; The Five Elements of—, 6; Notation of—, 7; Opposite and Reverse—, 8; Primary—, 11; Primary Mundane—12; Primary Zodiacal—7, 54; Secondary—, 73; Scale of the Aspect Extents of—, 16; —to the Angles, 19;—to Zodiacal Parallel, 60:—Zodiacal Rapt Parallel, 60.

Distance, Meridional—of D.B., 38. Diurna Map, 113;—Rotation, 96.

E

Epochal Aspects, 100; Determination of all the—on a given date, 101.

Exercise (1), 1;—(2) & (3), 2,—(4) to (6), 3;—(7) and (8), 5;—(9) to (18), 29;—(19) to (35), 30;—(36) to (38), 33;—(39) to (41), 36;—(42) to (48), 46;—49, 52;—(50) and (51), 53;—(52) to (59), 66;—(60), 160,
